

**Summary: sufficient conditions for  $x_*$  strict local minimizer**

---

**I.** Min  $f(x)$

$$\begin{cases} \nabla f(x_*) = \vec{0} \\ \nabla^2 f(x_*) \text{ positive definite} \end{cases}$$

---

**II.** Min  $f(x)$  subject to  $Ax = b$  (linear equality constraints, rows of  $A$  are linearly independent)

$$\begin{cases} Ax_* = b \\ Z^T \nabla f(x_*) = \vec{0} \Leftrightarrow \nabla f(x_*) = A^T \lambda_* \\ Z^T \nabla^2 f(x_*) Z \text{ positive definite} \end{cases}$$

( $Z$  is a null space basis matrix of  $A$ ).

---

**III.** Min  $f(x)$  subject to  $Ax \geq b$  (linear inequality constraints)

$$\begin{cases} Ax_* \geq b \\ \nabla f(x_*) = A^T \lambda_* \\ \lambda_* \geq \vec{0} \\ \text{strict complementarity } (\lambda_{*,i} = 0 \text{ iff inequality } i \text{ inactive constraint}) \\ Z^T \nabla^2 f(x_*) Z \text{ positive definite} \end{cases}$$

( $Z$  is a null space basis matrix of  $\hat{A}$ , submatrix of active constraints at  $x_*$ ,  $\hat{A}$  has lin. ind. rows).

---

**IV.** Min  $f(x)$  subject to  $g(x) = (g_1(x) \dots g_m(x))^T = \vec{0}$  (nonlinear equality constraints)

Let  $\mathcal{L}(x, \lambda) = f(x) - \sum_{i=1}^m \lambda_i g_i(x) = f(x) - \lambda^T g(x)$  and  $Z(x_*)$  be a null space basis matrix of  $\nabla g(x_*)^T$  (assume that gradients  $\nabla g_i(x_*)$  are lin. ind.)

$$\begin{cases} g(x_*) = \vec{0} \\ \nabla_x \mathcal{L}(x_*, \lambda_*) = 0 \\ Z(x_*)^T \nabla_{xx}^2 \mathcal{L}(x_*, \lambda_*) Z(x_*) \text{ positive definite} \end{cases}$$

---

**V.** Min  $f(x)$  subject to  $g(x) = (g_1(x) \dots g_m(x))^T \geq \vec{0}$  (nonlinear inequality constraints)

Let  $\mathcal{L}(x, \lambda) = f(x) - \sum_{i=1}^m \lambda_i g_i(x) = f(x) - \lambda^T g(x)$  and  $Z(x_*)$  be a null space basis matrix of the submatrix of  $\nabla g(x_*)^T$  corresponding to active constraints (assume gradients  $\nabla g_i(x_*)$  of active constraints  $g_i(x_*) = 0$  are lin. ind.)

$$\begin{cases} g(x_*) \geq \vec{0} \\ \nabla_x \mathcal{L}(x_*, \lambda_*) = 0 \\ \lambda_* \geq \vec{0} \\ \text{strict complementarity } (\lambda_{*,i} = 0 \text{ iff inequality } i \text{ inactive constraint}) \\ Z(x_*)^T \nabla_{xx}^2 \mathcal{L}(x_*, \lambda_*) Z(x_*) \text{ positive definite} \end{cases}$$

---

**REMARKS:**

- If  $\nabla^2 f(x_*)$  positive definite, then  $Z^T \nabla^2 f(x_*) Z$  is also positive definite (converse not true).
- If the matrix  $A$  (or  $\hat{A}$ ) is non-singular (i.e.  $\text{Null}(A)$  is the empty set), then  $Z$  does not exist, and the condition  $Z^T \nabla^2 f(x_*) Z$  is trivially satisfied.
- In IV and V,  $\nabla g(x_*)^T$  plays the role of the matrix  $A$ , when  $g(x) = Ax - b$ , and  $\nabla_{xx}^2 \mathcal{L}(x_*, \lambda_*)$  plays the role of  $\nabla^2 f(x_*)$ .
- Recall:  $\nabla \vec{g}(x)^T$  has the gradients  $\nabla g_i(x)$  written as rows.
- “Negative definite” instead of “positive definite” for local maximizer (and  $\lambda \leq 0$  for inequality constraints).
- For III and V, the textbook gives other sufficiency conditions for the case of degenerate constraints (Lemma 14.5 and Thm. 14.4).
