## Math 273b: Calculus of Variations Homework #3, due on Friday, June 3rd

[1] Consider the 1D length functional minimization problem

$$\min_{u} F(u) = \int_{0}^{1} L(u'(x)) dx, \text{ or } \min_{u} \int_{0}^{1} \sqrt{1 + (u'(x))^{2}} dx,$$

for twice differentiable functions  $u : [0,1] \to \mathbb{R}$  with boundary conditions u(0) = 0, u(1) = 1.

(a) Show that the functional  $u \mapsto F(u)$  is convex.

(b) Formally compute the Gateaux-differential and then obtain the Euler-Lagrange equation associated with the minimization.

(c) Find the exact solution of the problem.

[2] Let  $A : \mathbb{R}^n \to \mathbb{R}^n$  be a linear self-adjoint operator,  $b \in \mathbb{R}^n$ , and consider the quadratic function for  $x \in \mathbb{R}^n$ 

$$x \mapsto q(x) := \langle Ax, x \rangle - 2\langle b, x \rangle.$$

Show that the three statements

(i)  $\inf\{q(x): x \in \mathbb{R}^n\} > -\infty$ 

(ii)  $A \ge O$  and  $b \in \text{Im}A$ .

(iii) the problem  $\inf\{q(x): x \in \mathbb{R}^n\} > -\infty$  has a solution are equivalent. When they hold, characterize the set of minimum points of q, in terms of the pseudo-inverse of A.

[3] Computation of the Euler-Lagrange equation.

(a) Consider the minimization problem

$$\inf_{u} F(u) = \int_{x_0}^{x_1} L(x, u(x), u'(x)) dx,$$

with  $u(x_0) = u_0$ ,  $u(x_1) = u_1$  given constants, and L a sufficiently smooth function. Obtain formally the Euler-Lagrange equation of the minimization problem that is satisfied by a smooth optimal u.

Hint: Consider smooth test functions v, such that  $v(x_0) = v(x_1) = 0$ . Since u is a minimizer, we must have  $F(u) \leq F(u+\varepsilon v)$  for all such sufficiently smooth functions v and every real  $\epsilon$ . Apply integration by parts to obtain the desired result. You should obtain a second-order differential equation. (b) Let now u(x,t) be a smooth solution of the time-dependent partial differential equation (PDE)

$$\frac{\partial u}{\partial t} = \frac{\partial}{\partial x} L_{u'}(x, u, u') - L_u(x, u, u'),$$

with  $u(x,0) = u_0(x)$  on  $(x_0, x_1)$  and  $u(x_0, t) = U_0$ ,  $u(x_1, t) = U_1$  for  $t \ge 0$ . Show that the function  $E(t) = F(u(\cdot, t))$  is decreasing in time, where  $F(u) = \int_{x_0}^{x_1} L(x, u, u') dx$ .

## **Optional problems**

[1] Consider the minimization problem

$$\inf_{u} F(u) = \int_{x_0}^{x_1} L(x, u(x), u'(x), u''(x)) dx,$$

with  $u(x_0) = u_0$ ,  $u(x_1) = u_1$ ,  $u'(x_0) = U_0$ ,  $u'(x_1) = U_1$  given, and L a sufficiently smooth function. As in the previous problem, derive the equation satisfied by a smooth optimal u. Choose test functions v in  $C^{\infty}[x_0, x_1]$  that satisfy  $v(x_0) = v(x_1) = v'(x_0) = v'(x_1) = 0$ . (you should obtain a fourthorder differential equation).

[2] Consider the minimization problem in two dimensions (x, y),

$$\inf_{u} E(u) = \int_{\Omega} L(x, y, u, u_x, u_y) dx dy, \quad u = g \text{ on } \partial\Omega,$$

where g is a given function on the boundary  $\partial \Omega$ , with  $\Omega$  a bounded and open region in the plane. Assume that the integrand L is differentiable.

(i) Show that a sufficiently smooth minimizer u formally satisfies the Euler-Lagrange equation

$$\frac{\partial}{\partial x}L_{u_x}(P) + \frac{\partial}{\partial y}L_{u_y}(P) - L_u(P) = 0$$

on  $\Omega$ , where  $P = (x, y, u(x, y), u_x(x, y), u_y(x, y))$ .

(ii) Apply the above result to the case when  $L(x, y, u_x, u_y) = u_x^2 + u_y^2 - 2fu$ .

Hint for (i): consider another test function v, such that v = 0 on  $\partial\Omega$ . Since u is a minimizer, we must have  $E(u) \leq E(u + \varepsilon v)$  for all such sufficiently smooth functions v and all real  $\epsilon$ . Apply integration by parts to obtain the desired result. Here,  $(u_x, u_y) = \nabla u$ .

## Notes:

• **Pseudo-Inverse.** If A is a symmetric (or self-adjoint) linear operator on X, then  $\text{Im}A^{\perp} = \text{Ker}A$ . Let  $p_{\text{Im}A}$  be the operator of orthogonal projection onto ImA. For given  $y \in X$ , there is a unique x = x(y) in ImA such that  $Ax = p_{\text{Im}A}y$ . Forthermore, the mapping  $y \mapsto x(y)$  is linear. This mapping is called the pseudo-inverse, or generalized inverse of A.

• Integration by Parts Formula. Let  $\Omega$  be an open and bounded subset of  $\mathbb{R}^d$ , with Lipschitz-continuous (or sufficiently smooth) boundary  $\partial\Omega$ . Let  $\vec{n} = (n_1, n_2, ..., n_d)$  be the exterior unit normal to  $\partial\Omega$ . Let me recall the following fundamental Green's formula, or integration by parts formula: given two functions u, v (with u, v, and all their 1st order partial derivatives belonging to  $L^2(\Omega)$ , or  $u, v \in H^1(\Omega)$ ), then

$$\int_{\Omega} uv_{x_i} dx = -\int_{\Omega} u_{x_i} v dx + \int_{\partial \Omega} uv n_i dS.$$
