1 The Haar basis

We shall construct a nice orthonormal basis of $L^2(\mathbb{R})$. An interval $[x, y)$ is called dyadic, if it is of the form $[2^k n, 2^k (n + 1))$ with integers $k$ and $n$. In other words, its length is an integral power of 2, and its distance to the origin is a multiple of its length. Each dyadic interval is closed on the lower end and open on the upper end. Let $\mathcal{I}$ denote the set of all dyadic intervals.

We list the following immediate and useful properties of dyadic intervals:

1. For each $x \in \mathbb{R}$ and $k \in \mathbb{Z}$ there is exactly one dyadic interval of length $2^k$ which contains $x$.

2. Each dyadic interval is the disjoint union of two dyadic intervals of half the length.

3. If two dyadic intervals have nonempty intersection, then one of them is contained in the other.

If $I$ is a dyadic interval, let $I_l$ and $I_u$ its lower and upper half, i.e., $I_l$ and $I_u$ are again dyadic intervals. For each dyadic interval we define the Haar function $h_I$ by

$$h_I = \frac{1}{|I|} (1_{I_l} - 1_{I_u})$$

where $1_I$ denotes the characteristic function of $I$.

Lemma 1 The set $\{h_I : I$ dyadic $\}$ is an orthonormal basis of $L^2(\mathbb{R})$.

Proof We have

$$\langle h_I, h_J \rangle = \frac{1}{|I|} \left( \int_{I_l} 1_{I_l}(x) \, dx + \int_{I_u} 1_{I_u}(x) \, dx \right) = 1$$

thus all Haar functions have norm 1. Assume $I$ and $J$ are two different dyadic intervals. If $I$ and $J$ are disjoint, then $\langle h_I, h_J \rangle = 0$ because the supports of $h_I$ and $h_J$ are disjoint. Assume that $I$ and $J$ are not disjoint. By symmetry we can assume...
that $J$ is contained in $I$. Since $I \neq J$, we conclude that $|J| < |I|$. Thus $|J| \leq |I_i|$ and $|J| \leq |I_u|$. Since $J$ intersects at least one of $I_i$ and $I_u$, we have that $J$ is contained in $I_i$ or $I_u$. Thus

$$\langle h_I, h_J \rangle = \pm \frac{1}{\sqrt{|I||J|}} \left( \int_{I_i} dx - \int_{I_u} dx \right) = 0$$

Thus we have seen that the Haar functions are pairwise orthogonal.

It remains to show that the Haar functions are a complete orthonormal set. We shall prove more generally that the closure of the linear span of all Haar functions is dense in $L^p$ for all $1 < p < \infty$. Fix $p$. By Hahn Banach we have to show that every continuous linear functional $f$ on $L^p$ (thus $f \in L^{p'}$) which vanishes on all Haar functions is already 0.

Fix $f \in L^{p'}$ such that $\langle f, h_I \rangle = 0$ for all $I$.

Let $I_0$ be any dyadic interval and define $c$ by

$$\int_{I_0} f(x) \, dx = c|I^0|$$

Assume $|I| = 2^{k_0}$. For $k > 0$ let $I^k$ be the unique dyadic interval of length $2^{k_0+k}$ which contains $I^0$. We claim that

$$\int_{I_k} f(x) \, dx = c|I_k|$$

for all $k \geq 0$ and prove this by induction. We conclude from $\langle f, h_{I^{k,k}} \rangle = 0$ that

$$\int_{I_i^k} f(x) \, dx = \int_{I_u^k} f(x) \, dx.$$

Since one of the intervals $I_i^k$ and $I_u^k$ is equal to $I_{k-1}$, both sides of this equation are equal to $c|I_{k-1}|$, which proves the induction statement for $k$. By Hölder’s inequality we have

$$|c||I_k| = \left| \int_{I_k} f(x) \, dx \right| \leq |I_k|^\frac{1}{p'} \|f\|_{p'}.$$

By letting $k$ tend to infinity we conclude $c = 0$.

Now let $J$ be any open interval in $\mathbb{R}$. It is the disjoint union of the collection of maximal dyadic intervals in $J$. (Every point in $J$ is contained in some dyadic interval contained in $J$, and two maximal such intervals are disjoint because none of them is contained in the other.) Thus we conclude

$$\int_J f(x) \, dx = 0.$$

By Lebesgue’s differentiation theorem, $f$ has an indefinite integral whose derivative is equal to $f$ almost everywhere. But the indefinite integral is constant by the previous observation, so $f$ is zero almost everywhere. Thus $f$ is 0. This finishes the proof of the lemma.

Thus we have also proved the following lemma

2
Lemma 2 The linear span of the Haar functions is dense in $L^p(\mathbb{R})$ for $1 < p < \infty$.

Observe that this statement is not true for $p = 1$, because taking the mean of a function is a continuous operation in $L^1(\mathbb{R})$, and all Haar functions have mean zero, whereas $L^1(\mathbb{R})$ certainly contains functions which do not have mean 0. The statement is also false for $p = \infty$, because all linear combinations of Haar functions are compactly supported, and the compactly supported functions are not dense in $L^\infty(\mathbb{R})$.

The set of Haar functions is also a minimal set of functions such that the closure of their linear span is dense in $L^p$. Namely, if we remove one Haar function $h_I$ from this set, $h_I \in L^p$ is a nonzero continuous linear functional that vanishes on all other Haar functions, which therefore do not span a dense subspace. In this sense $\{h_I : I \text{ dyadic}\}$ is a basis of $L^p$.

Let $\mathcal{H}(\mathbb{R})$ denote the linear span of the Haar functions, i.e., the set of all finite linear combinations of Haar functions. Let $f \in L^p(\mathbb{R})$ and assume $f_i \in \mathcal{H}(\mathbb{R})$ converge to $f$ as $i \to \infty$. For each $i$ write

$$f_i = \sum_I a_I^{(i)} h_I,$$

where $a_I^{(i)} \neq 0$ only for finitely many $I$. Then an easy calculation gives

$$\lim_{i \to \infty} a_I^{(i)} = \lim_{i \to \infty} \left( \sum_J a_J^{(i)} h_J, h_I \right) = \langle f, h_I \rangle.$$

Therefore we would like to write

$$f = \sum_I \langle f, h_I \rangle h_I.$$

In $L^2$, this infinite sum is easily interpreted and shown to be well behaved by Hilbert space techniques, but in $L^p$, convergence of this infinite sum is not so clear, e.g. it may depend on the order of summation. We will come back to this issue later.

2 The Calderon Zygmund decomposition

We begin to prove estimates in $L^p$ involving expansions of Haar functions. The operator $T_\epsilon$ in the following lemma is a discrete model for what is called a singular integral operator in Fourier analysis.

Lemma 3 Let $\{\epsilon_I : I \text{ dyadic}\}$ be a collection of numbers bounded by 1. Then the operator

$$T_\epsilon f = \sum_I \epsilon_I \langle f, h_I \rangle h_I$$

mapping $\mathcal{H}(\mathbb{R})$ to itself extends to a bounded operator on $L^p(\mathbb{R})$ for all $1 < p < \infty$. More precisely, we have

$$\|T_\epsilon f\|_p \leq C_p\|f\|_p$$

with a constant $C_p$ depending only on $p$. 

The statement of this lemma can be expressed by saying that \( \{h_I\} \) is an unconditiona\( \text{t} \) basis of \( L^p \).

**Proof** For \( p = 2 \) the lemma follows trivially from the fact that the Haar functions are an orthonormal basis of \( L^2(\mathbb{R}) \). Namely, we have

\[
\|T_\epsilon f\|_2^2 = \sum_I |\epsilon I \langle f, h_I \rangle|^2 \leq \sum_I |\langle f, h_I \rangle|^2 = \|f\|_2^2 .
\]

We observe that it suffices to prove the lemma for \( 1 < p < 2 \). Namely, suppose it is true for some \( 1 < p < 2 \), we conclude by duality and self adjointness of \( T_\epsilon \) that it is also true for \( p' \):

\[
\|T_\epsilon f\|_{p'} = \sup_{g \in \mathcal{H}(\mathbb{R}) : \|g\|_{p'} = 1} \langle T_\epsilon f, g \rangle = \sup_{\|g\|_{p'} = 1} \sum_I \langle f, h_I \rangle \langle h_I, g \rangle \leq \sup_{\|g\|_{p'} = 1} \|f\|_{p'} \left\| \sum_I \langle g, h_I \rangle h_I \right\|_{p'} \leq C_p \|f\|_{p'} .
\]

By the Marcinkiewicz interpolation lemma (see next section and a technical remark further down) it suffices to prove the following so-called weak type 1, 1 estimate for the operator \( T_\epsilon \):

\[
|\{ x : |T_\epsilon f(x)| > \lambda \} | \leq C \lambda^{-1} \|f\|_1 .
\]

Let \( \mathcal{I}' \) be the collection of all maximal dyadic intervals such that

\[
(1) \quad \int_I |f(x)| \, dx > \lambda |I| .
\]

Then the intervals in \( \mathcal{I}' \) are pairwise disjoint, because if two such intervals were not disjoint, one was contained in the other and therefore not maximal. Thus we have

\[
\sum_{I \in \mathcal{I}'} |I| \leq \lambda^{-1} \sum_{I \in \mathcal{I}'} |f(x)| \, dx \leq \lambda^{-1} \int_{\mathbb{R}} |f(x)| \, dx \leq \lambda^{-1} \|f\|_1 .
\]

By a similar argument, we see that each interval satisfying (1) has length bounded by \( \lambda^{-1} \|f\|_1 \), and is thus contained in a maximal interval satisfying (1) (there are not infinite increasing chains of such intervals).

For each \( I \in \mathcal{I}' \) define

\[
b_I = \sum_{J \subseteq I} \langle f, h_J \rangle h_J .
\]

Observe that \( b_I \) is supported in \( I \) and has mean 0. If \( J \) is a dyadic interval not contained in \( I \), then \( h_J \) is constant on \( I \), and therefore \( \langle b_I, h_J \rangle = 0 \). Thus \( T_\epsilon b_I \) is supported in \( E = \bigcup_{I \in \mathcal{I}'} I \). Define

\[
g = f - \sum_{I \in \mathcal{I}'} b_I ,
\]

then it remains to show that

\[
(2) \quad |\{ x : |T_\epsilon g(x)| > \lambda \} | \leq C \lambda^{-1} \|f\|_1 .
\]

4
We shall prove that $|g|$ is bounded by $2\lambda$. Assume this is correct, then we have

$$\|g\|_2^2 = \int |g(x)|^2 \, dx$$

$$\leq 2\lambda^2 |E| + 2 \int_{\mathbb{R}\setminus E} |g(x)||\lambda| \, dx$$

$$\leq 2\lambda \|f\|_1 + 2 \int_{\mathbb{R}\setminus E} |f(x)||\lambda| \, dx \leq 4\lambda \|f\|_1 .$$

This gives

$$\|T_\epsilon g\|_2^2 \leq \|g\|_2^2 \leq 4\lambda \|f\|_1 .$$

This implies (??) by Chebyshev’s inequality, which states that for any function $F$ and any $0 < p < \infty$

$$|\{x : |F(x)| > \lambda\}| \lambda^p \leq \int_{\mathbb{R}} |F(x)|^p \, dx .$$

To see that $|g|$ indeed is bounded by $2\lambda$, let $J$ be any dyadic interval. If $J$ is not contained in any $I \in \mathcal{T}$, then $1_J$ is constant on any $I \in \mathcal{T}$. Therefore $\int_J b_I(x) \, dx$ vanishes for all $I \in \mathcal{T}$ and we have

$$\left| \int_J g(x) \, dx \right| = \left| \int_J f(x) \, dx \right| \leq \lambda |J|$$

by definition of $\mathcal{T}$. If $J$ is contained in some $I \in \mathcal{T}$, then, because $g$ is constant on $I$ and equal to the average of $f$ over $I$,

$$\left| \int_J g(x) \, dx \right| = \frac{|J|}{|I|} \left| \int_I f(x) \, dx \right| \leq \frac{|J|}{|I|} \int_I |f(x)| \, dx$$

Let $I'$ be the dyadic interval of length $2|I|$ containing $I$. Then we have, again by definition of $\mathcal{T}$:

$$\left| \int_J g(x) \, dx \right| \leq \frac{|J|}{|I|} \int_{I'} |f(x)| \, dx \leq \frac{|J|}{|I|} \lambda |I'| = 2\lambda |J| .$$

Thus the average of $f$ over any dyadic interval is bounded by $2\lambda$. Since $f \in \mathcal{H}(\mathbb{R})$, this proves that $f$ is bounded by $2\lambda$.

This completes the proof of this lemma, up to the Marcinkiewicz interpolation theorem which will be proved in the next section.

Technical remark: In order to apply the Marcinkiewicz interpolation operator, we need to extend the operator to a slightly larger space than $\mathcal{H}(\mathbb{R})$. Let $\Delta(\mathbb{R})$ denote the linear span of the characteristic functions of all dyadic intervals. It is easy to see that $\Delta(\mathbb{R}) = \mathcal{H}(\mathbb{R}) + \mathbb{R}1_{[0,1]} + \mathbb{R}1_{[-1,0]}$. We easily observe that for any numbers $\epsilon_I \in [-1, 1]$ the sum

$$\sum_I \epsilon_I \langle 1_{[0,1]}, h_I \rangle h_I$$

converges pointwise regardless of the order of summation and similar for the function $1_{[-1,0]}$. This defines $T_\epsilon(f)$ for $f \in \Delta(\mathbb{R})$ as a measurable function.
Since $\Delta(R) \subset L^2(R)$, $T_\epsilon$ satisfies the $L^2$ bound on $\Delta(R)$. We prove that $T_\epsilon$

satisfies the weak type $1,1$ estimate on $\Delta(R)$. First we observe

$$
|T_\epsilon(1_{[0,1]})| \leq \sum_{k \geq 0} 2^{-k} 1_{[0,2^k]} \leq \frac{1}{|x|},
$$

so the weak type estimate is satisfied for functions in the space $R^1_{[0,1]}$. Moreover we have for any $f \in H(R)$:

$$
\left| \left\{ |T_\epsilon(f + c1_{[0,1]})| > \lambda \right\} \right| \leq \left\{ |T_\epsilon f| > \frac{\lambda}{2} \right\} + \left\{ |cT_\epsilon 1_{[0,1]}| > \frac{\lambda}{2} \right\}
$$

$$
\leq CL^{-1}\|f\|_1 + C\lambda^{-1}c \leq C\lambda^{-1}\max(||f||_1, c) \leq C\|f + c1_{[0,1]}\|_1.
$$

Here the last inequality follows from the fact that $f$ has mean zero and thus

$$
|c| = \int_0^\infty (f(x) + c1_{[0,1]}(x)) dx \leq \|f + c1_{[0,1]}\|_1
$$

$$
\|f\|_1 = 2\int_{|f| > 0} |f(x)| dx \leq 2\int_{|f| > 0} |f(x) + c1_{[0,1]}(x)| dx \leq 2\|f + c1_{[0,1]}\|_1.
$$

Similarly we proceed with functions in $R^1_{[-1,0]}$ and thus conclude the weak type $1,1$ estimate for all of $\Delta(R)$. Thus we can apply the Marcinkiewicz interpolation theorem to the extended operator.

Remark: The function $g$ in this proof is called the good function at level $\lambda$, and the function $b = f - g = \sum_{I \in X} b_I$ is called the bad function. The crucial properties of these functions are that $g$ is bounded and thus the $L^2$ result can be applied, whereas $b$ is built up from mean 0 functions, which makes the operator $T_\epsilon$ act locally on the building blocks of $b$. The decomposition of $f$ into $g$ and $b$ is called the Calderon-Zygmund decomposition at level $\lambda$.

3 Marcinkiewicz interpolation lemma

Suppose $f \in L^p(R)$. Then we have Chebyshev’s inequality:

$$
|\{x : |f(x)| > \lambda\}| \lambda^p \leq \|f\|_p^p.
$$

On the other hand, we can write by Fubini

$$
\int |f(x)|^p dx = \int_0^{\infty} \int_{0 < \lambda \leq |f(x)|} p\lambda^{p-1} 1 \, d\lambda dx
$$

$$
= \int_0^{\infty} \int_{|f(x)| > \lambda} p\lambda^{p-1} 1 \, d\lambda dx = p \int_0^{\infty} \lambda^p \left| \{x : |f(x)| > \lambda\} \right| \frac{d\lambda}{\lambda}
$$

If the measure space $[0, \infty]$ with measure $d\lambda/\lambda$ had finite measure, then we could conclude the converse of Tschebyscheff’s inequality with some constant $C_p$. This of course is not the case, but on the range of power functions, $\lambda^{-1}$ only fails barely to be integrable at 0 and $\infty$. This is one of the themes behind the following interpolation lemma.
Lemma 4 Let $T$ be a sublinear operator mapping $\Delta(\mathbb{R})$ to the set of measurable functions on $\mathbb{R}$. (Sublinear means that

$$|T(f_1 + f_2)(x)| \leq |T(f_1)(x)| + |T(f_2)(x)|$$

for almost every $x$.) Let $1 \leq p_\prec < p_\succ < \infty$ and assume that there is a constant $C$ such that for $j \in \{<, >\}$ we have

$$|\{x : T f(x) > \lambda\}| \leq C \lambda^{-p_j} \|f\|_{p_j}^{p_j}.$$ 

Then $T$ extends to a bounded operator from $L^p$ to $L^p$ for every $p_\prec < p < p_\succ$, i.e.,

$$\|T f\|_p \leq C_p \|f\|_p$$

with a constant $C_p$ depending only on $C$, $p_\prec$, $p_\succ$, and $p$.

Remark: the constant $C_p$ in general tends to $\infty$ as $p$ tends to $p_\prec$ or $p_\succ$.

Proof

By multiplying $T$ with a constant we can assume $C = 1$ for $j \in \{<, >\}$. Let $f \in \Delta(\mathbb{R})$ and assume $\|f\|_p = 1$.

The idea of the proof is to decompose $f$ into small part and large part and control the small part by the $p_\succ$-norm and the large part by the $p_\prec$-norm.

Thus, for each $\lambda$ define

$$f_\succ = \max(f, \lambda) \quad ,$$

$$f_\prec = f - f_\succ \quad .$$

Then we have

$$p_\succ^{-1} \|f_\succ\|_{p_\succ}^{p_\succ} = \int_0^\infty \kappa^{p_\succ} \left|\{\|f_\succ\| > \kappa\}\right| \frac{d\kappa}{\kappa} = \int_{\lambda_1}^\infty \kappa^{p_\succ} \left|\{\|f\| > \kappa\}\right| \frac{d\kappa}{\kappa}$$

$$p_\prec^{-1} \|f_\prec\|_{p_\prec}^{p_\prec} \leq \int_0^\infty (\kappa + \lambda)^{p_\prec} \left|\{\|f_\prec\| > \kappa\}\right| \frac{d\kappa}{\kappa + \lambda} \leq \int_{\lambda_1}^\infty \kappa^{p_\prec} \left|\{\|f\| > \kappa\}\right| \frac{d\kappa}{\kappa}$$

We do the decomposition

$$|\{T f(x) > \lambda\}| \leq \sum_{j \in \{<, >\}} \left|\left\{x : T f_j > \frac{\lambda}{2}\right\}\right| \quad .$$

Each term on the right hand side is estimated by (here $C_p$ depends on $p$, $p_\succ$, $p_\prec$)

$$2^{p_j} \lambda^{-p_j} \|f_j\|_{p_j}^{p_j}$$

$$\leq C \int_{\kappa_1}^\infty \lambda^{-p_j} \kappa^{p_j} \left|\{\|f\| > \kappa\}\right| \frac{d\kappa}{\kappa} \quad .$$

Thus we have

$$\|T f\|_p = p \int \lambda^p \left|\{\|f\| > \lambda\}\right| \frac{d\lambda}{\lambda} \quad .$$
\[
\leq C_p \sum_{j} \int \int_{\Delta j} \lambda^{p-p_j} \kappa^{p_j} \{ |f| > \kappa \} \frac{d\lambda}{\lambda} \frac{d\kappa}{\kappa} .
\]

\[
\leq C_p \sum_{j} \kappa^{p_j} \{ |f| > \kappa \} \frac{d\kappa}{\kappa} .
\]

\[
= C_p \|f\|_p^p .
\]

This proves the lemma.

\[\blacksquare\]

4 The Littlewood Paley Square function

The Calderon-Zygmund type Lemma ?? which we proved earlier is closely related to the following lemma. Indeed, if we estimate \(\|T_\varepsilon f\|_p\) and \(\|f\|_p\) as in Lemma ?? from above and below by the expression given by the following lemma, then boundedness of \(T_\varepsilon\) follows immediately. Conversely, we will see in the next section, that Lemma ?? can be deduced from Lemma ?? with the aid of Khintchine’s inequality. However, we prove Lemma ?? directly, because we plan to deduce Khintchine’s inequality from it.

**Lemma 5** Let \(f \in \mathcal{H}(\mathbb{R})\) and \(1 < p < \infty\). Then

\[
\frac{1}{C} \|f\|_p \leq \left\| \left( \sum_I \frac{\langle f, h_I \rangle |I|}{|I|} 1_I \right) \right\|_p \leq C \|f\|_p
\]

In view of this lemma we define the square function \(Sf\) of \(f\) by

\[
Sf = \left( \sum_I \frac{\langle f, h_I \rangle |I|}{|I|} 1_I \right)^{\frac{1}{2}} .
\]

The lemma states that the \(L^p\) norms of \(f\) and \(Sf\) are comparable.

**Proof** For \(p = 2\) we have

\[
\|Sf\|_2^2 = \int \left( \sum_I \frac{\langle f, h_I \rangle |I|}{|I|} 1_I(x) \right)^2 dx = \sum_I |\langle f, h_I \rangle |^2 = \|f\|_2^2 .
\]

We observe that it suffices to prove the second inequality in (??) for all \(1 < p < \infty\), because then we obtain

\[
\|f\|_p = \sup_{g \in \mathcal{H}(\mathbb{R}) : \|g\|_p = 1} \langle f, g \rangle = \sup_g \sum_I \langle f, h_I \rangle \langle h_I, g \rangle
\]

\[
\leq \sup_g \int \sum_I |\langle f, h_I \rangle| |\langle h_I, g \rangle| 1_I(x) dx
\]

\[8\]
\[
\leq \sup_g \left\| \left( \sum_I \frac{|\langle f, h_I \rangle|^2}{|I|^\frac{2}{p}} 1_I \right)^{\frac{p}{2}} \left( \sum_I \frac{|\langle g, h_I \rangle|^2}{|I|^\frac{2}{p'}} 1_I \right)^{\frac{p'}{2}} \right\|_{p'}
\leq C\|Sf\|_p
\]

We prove the second inequality in (??). For \(1 < p < 2\) the proof is again done by interpolation with a weak type 1,1 estimate, which itself is proved by a Calderon Zygmund decomposition. The essential property of \(S\) that we need for this is that if \(b\) is supported on an interval \(I\) and has mean zero, then \(Sb\) is supported on \(I\). This is obviously the case. We shall omit further details.

In the proof of Lemma ?? we used duality to pass to estimates for \(2 < p < \infty\). Since taking the square function is not a linear operation, this idea is not immediately applicable here. One could bypass the nonlinearity by interpreting the square function as the norm of a vector valued linear operator. We shall take a different route and prove the estimate for \(2 < p < \infty\) directly.

Let \(f \in \Delta(\mathbb{R})\). It is easy to see that the sum defining \(f\) converges pointwise absolutely (and in \(L^2\)) to a function in \(L^2\), which is constant on small dyadic intervals. Define

\[E_\lambda := \{x : Sf(x) > \lambda\}\]

and let \(\mathcal{I}_\lambda\) be the collection of maximal dyadic intervals contained in \(E_\lambda\). Let \(\gamma\) be a small constant to be determined and call a \(I \in \mathcal{I}_\lambda\) exceptional if

\[\|f1_I\|_2 \leq \gamma\lambda|I|^\frac{1}{2} .\]

If \(I\) is not exceptional, we have with Hölder’s inequality:

\[\gamma\lambda|I|^\frac{1}{2} \leq \|f1_I\|_p .\]

Assume \(I \in \mathcal{I}_\lambda\) is exceptional and let \(I'\) be the dyadic interval of length \(2|I|\) containing \(I\). Then we have for \(x \in I\)

\[Sf(x)^2 = \sum_{J \subseteq I} \frac{|\langle f, h_J \rangle|^2}{|J|} 1_J(x) + \sum_{I' \subseteq J} \frac{|\langle f, h_J \rangle|^2}{|J|} 1_J(x)\]

\[\leq \sum_{J \subseteq I} \frac{|\langle f1_I, h_J \rangle|^2}{|J|} 1_J(x) + \lambda^2\]

The last inequality follows because \(I' \not\in E_\lambda\). This gives

\[|\{x \in I : Sf(x) > 2\lambda\}|\]

\[\leq \left| \left\{ x \in I : \sum_{J \subseteq I} \frac{|\langle f, h_J \rangle|^2}{|J|} 1_J(x) > \lambda^2 \right\} \right| \leq \frac{\|f1_I\|^2}{\lambda^2} \leq \gamma^2|I|\]

This gives

\[|E_{2\lambda}| \leq \sum_{I \not\in \mathcal{I}_\lambda, I \text{ not exc.}} |I| + \sum_{I \in \mathcal{I}_\lambda, I \text{ exc.}} \gamma^2|I|\]

9
Assume we have for certain \( \lambda \) that

\[
|E_{\lambda}| \leq 8 \cdot 2^p \frac{\|f\|_p^p}{\lambda^p},
\]

then (4) shows that (5) also holds for \( \lambda \) replaced by \( 2\lambda \). However for very small \( \lambda \) inequality (5) is satisfied because, for fixed \( f \in \Delta(\mathbb{R}) \), we have

\[
|E_{\lambda}| \leq \frac{\|f\|_2^2}{\lambda^2},
\]

which for small \( \lambda \) turns into (5).

Inequality (4) is a weak type \( p,p \) inequality for the sublinear operator \( S \). By Marcinkiewicz interpolation we obtain boundedness of \( S \) in \( L^q \) for \( 2 < q < p \). Since \( p < \infty \) was arbitrary, this finishes the proof. \( \blacksquare \)

At this point we return to the question of expanding arbitrary \( L^p \) functions into Haar series. Lemma 2 has the following striking consequences.

Let \( a_I \) be a collection of numbers and let \( \mathcal{I}_n \) be an increasing family of finite subsets of \( \mathcal{I} \) with \( \bigcup_n \mathcal{I}_n = \mathcal{I} \). Then the sequence

\[
\left\| \left( \sum_{I \in \mathcal{I}_n} \frac{|a_I|^2}{|I|} 1_I \right)^{\frac{1}{2}} \right\|_p
\]

is monotone increasing. Assume the limit is finite. By Lebesgue dominated convergence theorem we find a function \( S \in L^p \) with

\[
S = \lim_n S_n = \lim_{n \to \infty} \left( \sum_{I \in \mathcal{I}_n} \frac{|a_I|^2}{|I|} 1_I \right)^{\frac{1}{2}}.
\]

Define

\[
E_{\epsilon,n} := \{ x : S_n(x) < (1 - \epsilon)S(x) \}
\]

For fixed \( 0 < \epsilon < \frac{1}{2} \), the sets \( E_{\epsilon,n} \) shrink to 0 as \( n \to \infty \). Hence

\[
\|S1_{E_{\epsilon,m}}\|_p \leq \epsilon
\]

for all \( m \) greater than or equal to some appropriate \( n \). Then we have for all \( n < m < m' \)

\[
\| \sum_{I \in \mathcal{I}_m'} a_I h_I - \sum_{I \in \mathcal{I}_m} a_I h_I \|_p = \| \sum_{I \in \mathcal{I}_m' \setminus \mathcal{I}_m} a_I h_I \|_p
\]

\[
\leq \left\| \left( \sum_{I \in \mathcal{I}_m' \setminus \mathcal{I}_m} \frac{|a_I|^2}{|I|} 1_I \right)^{\frac{1}{2}} \right\|_p
\]
\[ \leq \left\| (S^2 - S_n^2)^{\frac{1}{2}} 1_{E_\xi, n} \right\|_p + \| S 1_{E_\xi, n} \|_p \]
\[ \leq \| (1 - (1 - \epsilon)^2)^{\frac{1}{2}} S \|_p + \epsilon \leq 2\epsilon^{\frac{1}{2}} \| S \|_p + \epsilon \]

This proves that
\[ f_n = \sum_{I \in \mathcal{I}_m} a_I h_I \]
is a Cauchy sequence in $L^p$. Let $f$ be its limit, then we have for each $I \in \mathcal{I}$:
\[ \langle f, h_I \rangle = \lim_{m} \langle f_m, h_I \rangle = a_I \]
hence the limit $f$ is what one expects and does not depend on the choice of the sequence $\mathcal{I}_n$. Vice versa, let $f \in L^p(\mathbb{R})$. We aim to prove that with $a_I := \langle f, h_I \rangle$ the sequence (??) has a finite limit. Let $f_n$ be a sequence of functions in $\mathcal{H}(\mathbb{R})$ such that $\|f - f_n\|_p \leq 2^{-n}$. Set $a_{I,n} = \langle f_n, h_I \rangle$. Then we have
\[ \left\| \left( \sum_I \frac{|a_{I,n}|^2}{|I|} 1_I(x) \right)^{\frac{1}{2}} \right\|_p \leq \left\| \left( \sum_I \frac{|a_{I,0} - a_{I,k-1}|^2}{|I|} 1_I \right)^{\frac{1}{2}} \right\|_p \]
\[ \leq C \| f_0 \|_p + C \sum_{k=1}^{n} \| f_k - f_{k-1} \|_p \leq C \sum_{k=0}^{n} 2^{-k} \leq C \]

Since obviously \( \lim_n a_{I,n} = a_I \), we easily see that for every finite subset $\mathcal{I}'$ of $\mathcal{I}$ we have for sufficiently large $n$ that $\mathcal{I}' \subset \mathcal{I}_n$ and
\[ \left\| \left( \sum_{I \in \mathcal{I}'} \frac{|a_I|^2}{|I|} 1_I \right)^{\frac{1}{2}} \right\|_p \leq 1 + \left\| \left( \sum_{I \in \mathcal{I}_n} \frac{|a_I|^2}{|I|} 1_I \right)^{\frac{1}{2}} \right\|_p \leq C \]

This proves (??) has a finite limit.

In particular, we see that if $f \in L^p$, then $\sum_I \langle f_I, h_I \rangle h_I$ converges to $f$ in $L^p$ regardless of the order of summation.

5 Khintchine’s inequality

Define the $k$-th Rademacher function on the interval $[0, 1)$ by
\[ r_0 = 1_{[0,1)} \]
\[ r_k = \sum_{I \in \mathcal{I} : I \subset [0,1], |I| = 2^{1-k}} |I|^{\frac{1}{2}} h_I \]

Thus the Rademacher function \( r_k \) has modulus 1 on the interval [0, 1) and oscillates between 1 and -1, taking each value on intervals of length \( 2^{-k} \).

**Lemma 6** Let \( (a_k)_{k \geq 0} \) be a sequence of coefficients with
\[
\sum_k |a_k|^2 < \infty
\]

Then \( \sum_{k=0}^{\infty} a_k r_k \) converges in \( L^p \) for all \( 0 < p < \infty \) and we have
\[
\frac{1}{C_p} \left( \sum_k |a_k|^2 \right)^{\frac{1}{2}} \leq \left\| \sum_k a_k r_k \right\|_p \leq C_p \left( \sum_k |a_k|^2 \right)^{\frac{1}{2}}
\]

for all \( 0 < p < \infty \).

Remark: Conversely, assume we didn't know that \( (a_k)_{k=0}^{\infty} \) is square summable, but \( \lim_{n \to \infty} \sum_{k=0}^{n} a_k r_k \) converges to a function in \( L^p \), \( 0 < p < \infty \). Then we have for each \( n \):
\[
\left( \sum_{k=0}^{n} |a_k|^2 \right)^{\frac{1}{2}} \leq C_p \left\| \sum_{k=0}^{n} a_k r_k \right\|_p \leq C_p ,
\]
hence \( (a_k) \) is square summable.

**Proof** Since the Rademacher functions are an orthonormal set of functions in \( L^2(\mathbb{R}) \) (beware: not complete), the inequality of the lemma holds in the case \( p = 2 \) with \( C_2 = 1 \). Define
\[
f = \sum_k a_k r_k .
\]

Assume \( 2 < p < \infty \). Then we have by Hölders' inequality
\[
\left( \sum_k |a_k|^2 \right)^{\frac{1}{2}} = \| f \|_2 \leq \| f \|_p .
\]

To obtain the reverse inequality, we apply Lemma ?? as follows:
\[
\| f \|_p \leq \left\| a_0 1_{[0,1]} \right\|_p + \left\| \sum_{k>0} \left( \sum_{|I|=2^{-k}, I \subset [0,1]} a_k |I_k|^{\frac{1}{2}} h_I \right) \right\|_p
\]
\[
\leq |a_0| + C \left\| \left( \sum_{k>0} \left( \sum_{|I|=2^{-k}, I \subset [0,1]} |a_k|^2 1_I \right) \right)^{\frac{1}{2}} \right\|_p = |a_0| + C \left\| \left( \sum_{k>0} |a_k|^2 1_{[0,1]} \right)^{\frac{1}{2}} \right\|_p
\]
\[
= |a_0| + C \left( \sum_{k>0} |a_k|^2 \right)^{\frac{1}{2}} \leq C \left( \sum_{k \geq 0} |a_k|^2 \right)^{\frac{1}{2}} .
\]
The finiteness of the square function in this line of arguments also implies the convergence of \( \sum_k a_k r_k \) in \( L^p \).

Now let \( 0 < p < 2 \). We have again by Hölder

\[
\|f\|_p \leq \|f\|_2 \leq \left( \sum_k |a_k|^2 \right)^{\frac{1}{2}} .
\]

Hölder’s inequality also implies that \( \sum_k a_k r_k \) converges in \( L^p \). It remains to show a lower bound for \( \|f\|_p \).

Pick \( 2 < q < \infty \). Since Khintchine’s inequality is already proven for \( q \) we have

\[
\|f\|_2 \leq \left\| f^1_{\{x : |f(x)| \leq \frac{1}{2} \|f\|_2 \}} \right\|_2 + \left\| f^1_{\{x : |f(x)| \geq \frac{1}{2} \|f\|_2 \}} \right\|_2 \\
\leq \frac{1}{2} \|f\|_2 + \|f\|_q \left\{ x : |f(x)| \geq \frac{1}{2} \|f\|_2 \right\}^{\frac{1}{2} - \frac{1}{q}} \\
\leq \frac{1}{2} \|f\|_2 + C \|f\|_2 \left\{ x : |f(x)| \geq \frac{1}{2} \|f\|_2 \right\}^{\frac{1}{2} - \frac{1}{q}}
\]

This implies

\[
\frac{1}{C} \leq \left\{ x : |f(x)| \geq \frac{1}{2} \|f\|_2 \right\} \leq C \frac{\|f\|_p}{\|f\|_2}.
\]

And thus

\[
\|f\|_2 \leq C \|f\|_p .
\]

Vice versa, we can use Khintchine’s inequality to deduce \( L^p \) bounds for the square function operator from Lemma ??.

Namely, let \( f \in \mathcal{H}(\mathbb{R}) \) and \( 1 < p < \infty \). Let \( I_1, I_2, \ldots \) be an enumeration of \( \mathcal{I} \). Then Lemma ?? implies that for each \( t \in [0, 1) \)

\[
\left\| \sum_{n=1}^\infty r_n(t) \langle f, h_{I_n} \rangle h_{I_n} \right\|_p \leq C_p \|f\|_p
\]

and hence

\[
\int_0^1 \left\| \sum_{n=1}^\infty r_n(t) \langle f, h_{I_n} \rangle h_{I_n} \right\|_p^p dt \leq C_p^p \|f\|_p^p .
\]

On the other hand we have with Khintchine’s inequality

\[
\int_0^1 \left\| \sum_{n=1}^\infty r_n(t) \langle f, h_{I_n} \rangle h_{I_n} \right\|_p^p dt \\
= \int_0^1 \int_0^1 \left\| \sum_{n=1}^\infty r_n(t) \langle f, h_{I_n} \rangle h_{I_n}(x) \right\|_p^p dt dx
\]

13
\[ \geq C \int_0^1 \left( \sum_{n=1}^\infty \left| \langle f, h_{tn} \rangle \right|^2 \left| h_{tn}(x) \right|^2 \right)^{\frac{p}{2}} \, dx \]
\[ = C \| Sf \|^p_p \]

This proves the square function estimate.

Observe that although Lemma ?? does not hold in the case \( p = 1 \), we can make the same argument as above for \( p = 1 \). Namely, if \( f \in \mathcal{H}(\mathbb{R}) \) and \( \| T_\epsilon f \|_1 \leq C \| f \|_1 \) for all choices \( \epsilon \in [-1, 1] \), then

\[ \| Sf \|_1 \leq C' \| f \|_1 \]

for a possibly different constant \( C' \). The \( L^1 \) norm of the square function will be further discussed in the following section about the Hardy space \( H^1(\mathbb{R}) \).

Finally, we point out the following probabilistic interpretation of expressions of the type \( f = \sum_{k=1}^n a_k r_k \). If for each \( 1 < k < n \) we flip a coin whether to add or subtract the number \( a_k \), then each possible event of this “Markov process” corresponds to an interval of length \( 2^{-n} \) in \([0, 1)\), on which \( f \) takes the value of the random sum corresponding to the event.

6 The Hardy space \( H^1 \) and BMO

The square function estimates show that we can identify the space \( L^p(\mathbb{R}) \) with the space \( H_p \) of all sequences \((a_I)_{I \in \mathcal{I}}\) which satisfy

\[ \| (a_I)_{I \in \mathcal{I}} \|_{H^p} := \left\| \left( \sum_I \frac{|a_I|^2}{|I|^p} \right)^{\frac{1}{p}} \right\| < \infty . \]

More precisely \( L^p \) and \( H^p \) are equivalent normed spaces if \( H^p \) is equipped with the norm \( \| . \|_{H^p} \).

Since the square function estimates break down at \( p = 1 \) and \( p = \infty \), we do no expect such an equivalence to be true for \( p = 1 \) or \( p = \infty \).

However one can study the spaces \( H^1 \) and \( H^\infty \) of all sequences \((a_I)_{I \in \mathcal{I}}\) which satisfy (??) with \( p = 1 \) or \( p = \infty \) respectively. Indeed \( H^1 \) and \( H^\infty \) are normed spaces with norms \( \| . \|_{H^1} \) and \( \| . \|_{H^\infty} \). (Of course one would like to think of an element \((a_I) \in H^1 \) or \( H^\infty \) as a function

\[ \sum_I a_I h_I , \]

and this can be done, but at this time the meaning of such an infinite sum has not been clarified.)

For \( 1 < p < \infty \), the dual space of \( H^p \) is \( H^{p'} \), as one can see from the identification with \( L^p \) and \( L^{p'} \). However, it turns out that \( H^\infty \) is not the dual space of \( H^1 \). The main purpose of the current section is to identify the dual space of \( H^1 \) which will be called BMO.
If $\lambda$ is a continuous linear functional on $H^1(\mathbb{R})$, denote by $b_I$ the number $\lambda((a_I)_{I \in \mathcal{I}})$ where $a_I = 1$ if $I = J$ and $a_I = 0$ otherwise. If $(a_I)_{I \in \mathcal{I}}$ is any sequence with finitely many nonzero entries, we then have

$$\lambda((a_I)_{I \in \mathcal{I}}) = \sum_I a_I b_I$$

Since the space of sequences with finitely many nonzero entries is dense in $H^1$ (Lebesgue dominated convergence), the sequence $(b_I)_{I \in \mathcal{I}}$ determines the functional $\lambda$. Vice versa, if $(b_I)_{I \in \mathcal{I}}$ is any sequence of real numbers, it extends to a bounded linear functional on $H^1$ if and only if

$$\left| \sum_I a_I b_I \right| \leq C \| (a_I)_{I \in \mathcal{I}} \|_{H^1}$$

for all sequences $(a_I)_{I \in \mathcal{I}}$ with finitely many nonzero entries. Thus we can identify the space $(H^1)^*$ with the space of all sequences $(b_I)_{I \in \mathcal{I}}$ satisfying (7). The norm

$$\| b_I \|_{(H^1)^*}$$

of an element in the dual space of $H^1$ is given by the best constant $C$ in (7). In what follows we shall give a more direct characterisation of the elements in the space $(H^1)^*$.

Suppose $\lambda = (b_I)_{I \in \mathcal{I}} \in (H^1)^*$. Let $J$ be any dyadic interval and assume $a_I$ vanishes when $I \not\subset J$. Then we have by Cauchy-Schwarz

$$\left| \sum_I a_I b_I \right| \leq \| \lambda \|_{(H^1)^*} \left\| \left( \sum_I \frac{|a_I|^2}{|I|} 1_I \right)^{\frac{1}{2}} \right\|_1$$

$$\leq \| \lambda \|_{(H^1)^*} |J|^{\frac{1}{2}} \left\| \left( \sum_I \frac{|a_I|^2}{|I|} 1_I \right)^{\frac{1}{2}} \right\|_2 = \| \lambda \|_{(H^1)^*} |J|^{\frac{1}{2}} \left( \sum_I |a_I|^2 \right)^{\frac{1}{2}}$$

Let $\mathcal{I}'$ be any finite collection of intervals contained in $J$ and set $a_I = b_I$ if $I \in \mathcal{I}'$ and $a_I = 0$ otherwise. Then the previous line of inequalities shows

$$\sum_{I \in \mathcal{I}'} |b_I|^2 \leq \| \lambda \|_{(H^1)^*} |J|^{\frac{1}{2}} \left( \sum_I |a_I|^2 \right)^{\frac{1}{2}}.$$ 

Taking the sup over all sets $\mathcal{I}'$ gives

$$\sum_{I \in \mathcal{I}'} |b_I|^2 \leq \| \lambda \|_{(H^1)^*} |J|^{\frac{1}{2}} \left( \sum_I |a_I|^2 \right)^{\frac{1}{2}}.$$ 

Thus a necessary condition for a sequence $(b_I)_{I \in \mathcal{I}}$ to be in $(H^1)^*$ is that the left hand side of (7) is bounded by a constant independently of $J$. The following lemma states that boundedness of the left hand side of (7) independently of $J$ is also sufficient for the sequence $(b_I)_I$ to be in $(H^1)^*$.
Lemma 7 A sequence \((b_I)_{I \in I}\) is an element of \((H^1)^*\) if and only if

\[
\sup_{J \in I} |J|^{-\frac{1}{2}} \left( \sum_{I \subseteq J} |b_I|^2 \right)^{\frac{1}{2}} < \infty .
\]

The quantity on the left hand side of (7) is a norm equivalent to the \((H^1)^*\) norm.

We call the quantity on the left hand side of (7) the BMO norm of the sequence \((b_I)_{I \in I}\) and write

\[
\| (b_I)_{I \in I} \|_{\text{BMO}}
\]

for it. The lemma states that the space BMO of all sequences with bounded BMO norm is equivalent to the space \((H^1)^*\) under the identity map.

Proof After the preceding discussion it remains to prove that there is a universal constant \(C\) such that for any sequences \(b_I\) and any finite sequence \(a_I\) we have

\[
\left| \sum_I a_I b_I \right| \leq C \|a_I\|_{H^1} \| (b_I)_{I \in I} \|_{\text{BMO}} .
\]

For each \(m \in \mathbb{Z}\) let

\[
E_m = \left\{ x : \left( \sum_{I \in I_m} \frac{|a_I|^2}{|I|} 1_I(x) \right)^{\frac{1}{2}} \geq 2^m \right\} .
\]

Let \(I_m\) be the set of dyadic intervals contained in \(E_m\) but not in \(E_{m+1}\), and let \(I_m^{\text{max}}\) be the set of maximal dyadic intervals contained in \(E_m\).

Then we have by Cauchy-Schwarz

\[
\left| \sum_I a_I b_I \right| \leq \sum_m \left( \sum_{I \in I_m} |a_I|^2 \right)^{\frac{1}{2}} \left( \sum_{I} |b_I|^2 \right)^{\frac{1}{2}}
\]

\[
\leq \sum_m \left( \int \sum_{I \in I_m} \frac{|a_I|^2}{|I|} 1_I(x) \, dx \right)^{\frac{1}{2}} \left( \| (b_I)_{I \in I} \|_{\text{BMO}} \sum_{I \in I_m^{\text{max}}} |I_m| \right)^{\frac{1}{2}}
\]

\[
\leq \| (b_I)_{I \in I} \|_{\text{BMO}} \sum_{m} \left( |E_m| 2^{2m} \right)^{\frac{1}{2}} (|E_m|)^{\frac{1}{2}}
\]

Here we have used that

\[
\left( \int \sum_{I \in I_m} \frac{|a_I|^2}{|I|} 1_I(x) \, dx \right)^{\frac{1}{2}}
\]

is bounded by \(2^{2m+1}\). This is clearly true on the complement of \(E_{m+1}\). Let \(J\) be a maximal dyadic interval in \(E_{m+1}\) and let \(J'\) be the dyadic intervals of length \(2|J|\) containing \(J\). Then clearly (8) is constant on \(J'\), and since \(J'\) is not contained in
\( E_{m+1}, \) (??) is bounded by \( 2^{m+1} \) on \( J' \). This shows that (??) is bounded by \( 2^{m+1} \) on \( E_{m+1} \). Now we easily see that

\[
\| (b_I)_J \|_{BMO} \sum_m \left( |E_m|2^{2m} \right)^{\frac{1}{2}} \left( |E_m| \right)^{\frac{1}{2}} = \| (b_I)_J \|_{BMO} \sum_m 2^m |E_m| \\
\leq 2 \| (b_I)_J \|_{BMO} \int_0^\infty \lambda \left\{ x : \left( \sum_I |a_I|^2 |I_1(x) \right)^{\frac{1}{2}} \geq \lambda \right\} d\lambda \\
= 2 \| (b_I)_J \|_{BMO} \left\| \left( \sum_I |a_I|^2 |I_1(x) \right)^{\frac{1}{2}} \right\|_L
\]

This finishes the proof of the lemma. □

7 The space BMO as function space

In this section we discuss how to make sense of the expression \( \sum_I b_I h_I \) as a function if \( (b_I)_J \) is a BMO sequence.

Thus let \( (b_I)_J \) be a sequence in BMO. For each \( n \geq 0 \) define \( I_n = [0, 2^n) \) and define a function \( f_n \) on \( I_n \) by

\[
f_n(x) = \sum_{I \subset I_n} b_I h_I(x) - \sum_{I_0 \subset I \subset I_n} b_I |I|^{-\frac{1}{2}}
\]

Obviously this sum converges in \( L^2 \): the first summand because of the BMO estimate, the second because it is a finite sum. Thus this expression as well as other expressions of this type below are understood to hold for almost every \( x \).

If \( n < n' \), then \( f_n \) and \( f_n' \) coincide on \( I_n \), because we have on \( I_n \)

\[
f_n'(x) = \sum_{I \subset I_n} b_I h_I(x) + \sum_{I_0 \subset I \subset I_n} b_I h_I(x) - \sum_{I_0 \subset I \subset I_n} b_I |I|^{-\frac{1}{2}} - \sum_{I_0 \subset I \subset I_{n'}} b_I |I|^{-\frac{1}{2}},
\]

which is equal to \( f_n(x) \) because the second and fourth term on the right hand side cancel each other on \( I_n \).

Thus we can define a function \( f \) on \( [0, \infty) \) by defining unambiguously

\[
f(x) = f_n(x)
\]

whenever \( 2^n > x \). Similarly we can define a function on \( (-\infty, 0] \), by first defining a sequence of functions on the intervals \( [-2^n, 0) \). This defines a function on all of \( \mathbb{R} \).

If \( I \) is any dyadic interval, define \( f_I \) to be the average of \( f \) on \( I \). Then we have

\[
\| f 1_I - f_I \|_2 \leq |I|^{\frac{1}{2}} \| (b_I)_J \|_{BMO}
\]

17
Namely, if $I \subset [0, \infty)$ say, then we have for some sufficiently large $n$ with $I \subset [0, 2^n)$
\[
f(x) - f_I(x) = f_n(x) - (f_n)_I(x)
\]
and
\[
f_n(x) = \sum_{J \subset I} b_I h_I + \sum_{I \subset J \subset I_n} b_I h_I - \sum_{b_I \subset J \subset I_n} b_I .
\]
The first term on the right hand side has mean zero on $I$, whereas the other two terms are constant on $I$ and therefore
\[
f_n(x) - (f_n)_I(x) = \sum_{J \subset I} b_I h_I .
\]
Thus (??) follows form the BMO property of the sequence $b_I$. The assignment $(b_I)_I \to f$ we have defined is injective, because one easily verifies
\[
b_I = \langle f, h_I \rangle ,
\]
so if $f = 0$ then $(b_I)_I = 0$.

Vice versa, let $g$ be any function locally in $L^2$ and satisfying
\[
|I|^{-\frac{1}{2}} \|f - f_I\|_{L^2(I)} \leq C
\]
Then we can define a sequence $(b_I)$ by
\[
b_I = \langle g, h_I \rangle .
\]
Then (??) implies that $b_I$ is a BMO sequence. This assignment $g \to (b_I)_I$ is not quite injective, because if $b_I = 0$ for all $I$, then all we can conclude is that if $J$ is any interval, then
\[
\sum_{I \subset J} \langle g, h_I \rangle h_I = 0
\]
in $L^2$ sense, and since $\{|J|^{-\frac{1}{2}} 1_J\} \cup \{h_I : I \subset J\}$ is an orthonormal basis of $L^2(J)$ we conclude $g$ is a constant on $I$ in $L^2$ sense. By letting $J$ being $[0, 2^n)$ and $[-2^n, 0)$ for larger and larger $n$ we conclude that $g$ coincides with a function
\[
c_+ 1_{[0, \infty)} + c_{-1(-\infty, 0]}
\]
almost everywhere.

By the above identifications, we can therefore identify BMO with the space of all locally $L^2$ functions satisfying (??) modulo the space $c_+ 1_{[0, \infty)} + c_{-1(-\infty, 0]}$. We will be somewhat sloppy and call these equivalence classes of functions themselves BMO-functions.

Obviously every function in $L^\infty$ defines a BMO-function because it is locally in $L^2$ and satisfies
\[
|I|^{-\frac{1}{2}} \|f - f_I\|_{L^2(I)} \leq |I|^{-\frac{1}{2}} (\|f_1I\|_2 + \|f_I 1_I\|_2) \leq 2\|f\|_\infty .
\]
Moreover, if \( f \in L^\infty \), then also
\[
f + c_+ 1_{[0,\infty)} + c_- 1_{(-\infty,0]} \in L^\infty,
\]
for all \( c_+ \) and \( c_- \), so \( L^\infty / \{c_+ 1_{[0,\infty)} + c_- 1_{(-\infty,0]}\} \) is a continuously imbedded subspace of BMO.

However, a function in BMO does not necessarily come from a function in \( L^\infty \), an example is given by the function
\[
f(x) = \log |x|
\]
Let \( I = [a, b) \) be a dyadic interval contained in \([0, \infty)\). We shall prove
\[
\|f - f_I\|_{L^2(I)} \leq \|f - f(b)\|_{L^2(I)} \leq C.
\]
The first inequality is clear by an orthogonality argument: the constant function is orthogonal to \( f - f_I \) in \( L^2(I) \) and thus
\[
\|f - f_I\|^2_{L^2(I)} = \|f - f(b)\|^2_{L^2(I)} + \|f_I - f(b)\|^2_{L^2(I)}.
\]
For the second inequality we shall decompose \( I = \bigcup_n I_n \) where \( I_1 \) is the right half of \( I \), \( I_2 \) is the right half of \( I \setminus I_1 \) and so on. Then \( I_n \) sits between \((1/2)^n b \) and \( b \), hence
\[
\log |x| - \log |b| \leq n \log(1/2)
\]
on \( I_n \). Thus
\[
\|f - f(b)\|_{L^2(I_n)} \leq C n |I_n|^\frac{1}{2} = C n 2^{-\frac{n}{2}} |I|^{\frac{1}{2}}
\]
Summing over \( n \) gives
\[
\|f - f(b)\|_{L^2(I)} \leq C |I|.
\]
A similar argument holds for intervals contained in \((-\infty, 0] \). This proves that \( \log |x| \) is a BMO function. However, \( \log |x| \) is not in \( L^\infty \) because it is unbounded near 0 and \( \infty \).

To make the point that \( H^\infty \) is not the dual of \( H^1 \), we present a function which is in \( L^\infty \) and thus in BMO, but whose square function is not in \( L^\infty \), therefore its sequence of coefficients \( \langle f, h_I \rangle \) is not in \( H^\infty \). Define
\[
f = \sum_{k \in \mathbb{Z}} 1_{[2^{2k}, 2^{2k+1})} - 1_{[2^{2k+1}, 2^{2k+2})}
\]
Then \( f \) is a bounded function. Obviously we have
\[
f(x) = -f(2x)
\]
Therefore an easy scaling argument shows that
\[
\langle f, h_{[0,2^1]} \rangle = (-1)^k c 2^{-\frac{k}{2}}.
\]
for a certain constant \( c \). Since \( f \) changes sign on the left half of \([0, 2^k]\) but not on the right half of \([0, 2^k]\) it follows that \( c \neq 0 \). Thus we have for the square function:

\[
\left( \sum_I \frac{|\langle f, h_I \rangle|^2}{|I|} 1_I \right) \geq \left( \sum_k c^2 1_{[0, 2^k]} \right)^{\frac{1}{2}}
\]

(It is actually not hard to see that we have equality here. The right hand side however is not in \( L^\infty \), since its values tend to \( \infty \) as \( x \) tends to +0.

The following definition shows that in the condition (??) for BMO functions we could have used any \( 0 < p < \infty \) instead of \( p = 2 \). As before we denote by \( f_I \) the average of \( f \) on \( I \).

**Lemma 8** Let \( f \in \text{BMO} \) and \( I \) an interval. Then

\[
\frac{1}{C_p} \| f - f_I \|_{L^p(I)} |I|^{-\frac{1}{p}} \leq \| f - f_I \|_{L^2(I)} |I|^{-\frac{1}{2}} \leq C_p \| f - f_I \|_{L^p(I)} |I|^{-\frac{1}{p}}
\]

and

\[
E_n = |\{ x \in I : |f(x) - f_I| \geq \lambda \}| \leq c_1 e^{c_2 n \left\| f \right\|_{\text{BMO}}} |I|
\]

**Proof** We first consider the case \( p > 2 \). Then the second inequality in (??) follows by Hölder, therefore it suffices to prove the first inequality.

Fix an interval \( I \). Let \( Sg \) denote the square function of \( g \). For any function \( g \in L^p(I) \) with mean 0 on \( I \) we have

\[
\left| \sum_I \langle f, h_I \rangle \langle g, h_I \rangle \right| 
\leq C \| f \|_{\text{BMO}} \| Sg \|_1 \leq C \| f \|_{\text{BMO}} \| Sg \|_p |I|^{1-\frac{1}{p}} \leq C \| f \|_{\text{BMO}} \| g \|_p |I|^{1-\frac{1}{p}}
\]

Thus there is an element \( f' \) in \( L^p(I) \) (which we can assume to have mean zero) such that

\[
\| f' \|_p \leq \| f \|_{\text{BMO}} |I|^{\frac{1}{p}}
\]

and

\[
\sum_I \langle f, h_I \rangle \langle g, h_I \rangle = \int_I f'(x)g(x) \, dx
\]

for all \( g \in L^p(I) \). Since for all \( g \in L^2(x) \) we have

\[
\sum_I \langle f, h_I \rangle \langle g, h_I \rangle = \int_I (f(x) - f_I)g(x) \, dx
\]

we conclude that \( f - f_I \) coincides with \( f' \) on \( I \). This proves the first inequality in (??).

For \( 0 < p < 2 \) the first inequality follows by Hölder, whereas the second inequality follows by a short calculation with Chebyshev’s inequality as we have done for Khinchine’s inequality. We omit further details.
It remains to prove (??). Using (??) we have for $p > 2$

$$|\{x \in I : |f(x) - f_I| > \lambda\}| \leq C\lambda^{-p} \|f'\|_p^p \leq C_p \lambda^{-p} \|f\|_{BMO}^p |I|$$

For small $\lambda$, (??) simply follows from $p = 2$. So far we have not discussed the constant $C_p$, but tracking it down we obtain the bound $C_p \leq (Ap)^p$ for some $A$ independent of $p$. This we leave as an exercise. For large $\lambda$ we pick $p$ so that $2Ap \|f\|_{BMO} = \lambda$. Then (??) follows again.

Inequality (??) is called the John-Nirenberg inequality. It clearly implies inequality (??).

8 Maximal truncated singular integrals

We consider again the discrete singular integral operators

$$T_\epsilon f = \sum_{I \in \mathcal{I}} \epsilon_I \langle f, h_I \rangle h_I,$$

which are well defined on $L^p$ for $1 < p < \infty$. Assume we wanted to calculate the value of $f(x)$, then we could write the following series:

$$\lim_{k \to \infty} \sum_{2^{-k} < |I| < 2^k} \epsilon_I \langle f, h_I \rangle h_I(x). \tag{16}$$

Since $h_I(x) \neq 0$ only if $x \in I$, the sum in this expression is really a finite sum. The expression

$$\sum_{2^{-k} < |I| < 2^k} \epsilon_I \langle f, h_I \rangle h_I$$

is called a (discrete) truncated singular integral.

Thus we are naturally interested in convergence of the truncated singular integrals. If $1 < p < \infty$ and $f \in L^p$, then all we know so far is $T_\epsilon f \in L^p$. Thus point evaluation makes only sense almost everywhere, and we can only expect this limit to exist almost everywhere.

The general approach to such almost everywhere convergence problems is to consider the corresponding maximal function

$$T_\epsilon^{\text{max}} f(x) := \sup_k \left| \sum_{|I| < 2^k} \epsilon_I \langle f, h_I \rangle h_I(x) \right|$$

This is a measurable function which takes values in $\mathbb{R}^+ \cup \{\infty\}$, it is also called the maximal truncated singular integral.

Suppose we knew the following lemma
Lemma 9 For all $1 < p < \infty$ there is a constant $C_p$ such that for all $f \in L^p(\mathbb{R})$ and all sequences $(\epsilon_I)_I$ with $|\epsilon_I| \leq 1$ for all $I$ we have

$$\|T^\text{max}_\epsilon f\|_p \leq C_p \|f\|_p$$

Then we could prove almost everywhere convergence to $f(x)$ of the series (??) as follows. We need to prove, that for each $\delta$ the series (??) converges to $f(x)$ outside a set of measure $\delta$. Thus we have to prove that for each $n$ there is a $k_0$ such that for all $k > k_0$ we have

$$\left| \left\{ x : \sum_{2^{-k} < |I| < 2^k} \epsilon_I \langle f, h_I \rangle h_I(x) - f(x) > 2^{-n} \right\} \right| \leq 2^{-n}\delta$$

because then the series converges outside a set of measure $\sum_n \delta 2^{-n} = C\delta$. Fix $\delta$ and $n$. Let $g \in \mathcal{H}(\mathbb{R})$ such that $\|f - g\|_p$ is smaller than a certain number depending on $p$, $\delta$, and $n$, and let $k_0$ be large enough so that

$$\sum_{2^{-k_0} < |I| < 2^{k_0}} \epsilon_I \langle g, h_I \rangle h_I = g$$

Then the above set can be estimated by

$$\left| \left\{ x : \sum_{2^{-k} < |I| < 2^k} \epsilon_I \langle f - g, h_I \rangle h_I(x) > 2^{-n-2} \right\} \right| +$$

$$\left| \left\{ x : \sum_{2^{-k} < |I| < 2^k} \epsilon_I \langle g, h_I \rangle h_I(x) - g(x) > 2^{-n-2} \right\} \right| +$$

$$\left| \left\{ x : |f(x) - g(x)| > 2^{-n-2} \right\} \right|$$

$$\leq C_p 2^{n+3} \|T^\text{max}_\epsilon (f - g)\|_p^p + 0 + C_p 2^{n} \|f - g\|_p^p$$

$$\leq C(p, n, \delta) \|f - g\|_p^p \leq \delta 2^{-n}$$

where the last inequality follows by appropriate choice of $g$. Thus we have almost everywhere convergence of the truncated singular integrals for all $f \in L^p$.

It remains to prove the Lemma ??.

Proof: Let $1 < p < \infty$ and $f \in L^p$, then

$$\tilde{f} = \sum_I \epsilon_I \langle f, h_I \rangle h_I$$

is in $L^p$ with $\|\tilde{f}\|_p \leq C \|f\|_p$, and we have

$$\epsilon_I \langle f, h_I \rangle = \langle \tilde{f}, h_I \rangle$$

By replacing $f$ by $\tilde{f}$ it therfore suffices to prove the lemma with $\epsilon_I = 1$ for all $I$. 22
If $J$ is an interval, then integrating over $J$ is a continuous operation in $L^p$ and we have
\[
|J|^{-1} \int_J f(y) \, dy
= |J|^{-1} \int_{|I| \geq |J|} \langle f, h_I \rangle h_I(y) \, dy
= \sum_{|I| \geq |J|} \langle f, h_I \rangle h_I(x)
\]
for each $x \in J$. Thus
\[
T_1^{\text{max}} f(x) = \sup_{J : x \in J} \frac{1}{|J|} \left| \int_J f(y) \, dy \right|
\]
This is bounded by the (dyadic) Hardy Littlewood maximal operator
\[
Mf(x) = \sup_{J : x \in J} \frac{1}{|J|} \int_J |f(y)| \, dy
\]
By Marcinkiewicz interpolation it suffices to prove a weak type $p, p$ estimate for the Hardy Littlewood maximal operator for all $1 \leq p < \infty$. (observe that trivially $M$ is bounded in $L^\infty$.)

Let $E_\lambda$ be the set where $Mf(x) > \lambda$. By definition of $f$, for each $x$ in this set there is a dyadic interval $I$ containing $x$ such that
\[
\lambda < |I|^{-1} \int_I |f(y)| \, dy \leq |I|^{-\frac{p}{2}} \|f1_I\|_p
\]
Let $T'$ be the collection of maximal dyadic intervals satisfying
\[
\|f1_I\|_p^p \geq \lambda^{-p} |I|
\].
Then we have
\[
|E_\lambda| \leq \sum_{I \in T'} |I| \leq \lambda^{-p} \sum_{I \in T'} \|f1_I\|_p^p \leq \lambda^{-p} \|f\|_p^p
\]
This proves the weak type $p, p$ estimate for the sublinear operator $M$ and thus finishes the proof of Lemma 222.

\section{Paraproducts and a discrete T1 theorem}

So far we have studied discrete singular integral operators of the type
\[
T_\epsilon f = \sum_I \epsilon_I \langle f, h_I \rangle h_I
\]
They are bounded in $L^p$ if and only if $\epsilon_I$ are bounded. The if part follows from square function estimates, whereas the only if part is easily seen from
\[
T_\epsilon h_I = \epsilon_I h_I
\].
To complete the picture, we need to study another type of discrete singular integral operators. For a sequence \((\epsilon_I)_I\) define for \(f \in \mathcal{H}(\mathbb{R})\)

\[
P_\epsilon f = \sum_I \langle f, \chi_I \rangle h_I ,
\]

where \(\chi_I = |I|^{-\frac{1}{2}}1_I\), and the infinite sequence is easily seen to converge pointwise absolutely if \(f \in \mathcal{H}(\mathbb{R})\). The operator \(P_\epsilon\) is called a discrete paraproduct and obviously has similar localization properties as \(T_\epsilon\). Again we would like to know for which sequences \(\epsilon_I\) the paraproduct (??) defines a bounded operator from \(L^p\) to \(L^p\). As a first observation, since the \(\chi_I\) do not form an orthonormal set in \(L^2\), we do not expect \(P_\epsilon\) to be bounded in \(L^2\) for all bounded sequences \(\epsilon_I\).

The answer to this question is given by

**Lemma 10** If \(|I|^{\frac{1}{2}}\epsilon_I\) is a BMO sequence, then the operator \(P_\epsilon\) satisfies

\[
\|P_\epsilon f\|_p \leq C_p \| (|I|^{\frac{1}{2}}\epsilon_I)_I \|_{\text{BMO}} \|f\|_p
\]

for \(1 < p < \infty\). Vice versa, if \(P_\epsilon\) is bounded in \(L^p\) for any \(1 < p < \infty\), then \(|I|^{\frac{1}{2}}\epsilon_I\) is a BMO sequence.

**Proof** Assume \(|I|^{\frac{1}{2}}\epsilon_I\) is a BMO sequence. Observe that

\[
|I|^{-\frac{1}{2}} |\langle f, \chi_I \rangle| 1_I \leq Mf .
\]

where \(M\) denotes the Hardy Littlewood maximal function. Thus we have, denoting by \(Sf\) the square function of \(f\),

\[
\|P_\epsilon f\|_p = \sup_{\|g\|_p = 1} \langle P_\epsilon f, g \rangle = \sum_I \epsilon_I \langle f, \chi_I \rangle \langle h_I, g \rangle
\]

\[
\leq \| (\epsilon_I)_I \|_{\text{BMO}} \left( \sum_I |\langle f, \chi_I \rangle \langle h_I, g \rangle|^2 |I|^{-1} 1_I \right)^{\frac{1}{2}}
\]

\[
\leq \| (\epsilon_I)_I \|_{\text{BMO}} \left( \sum_I |\langle h_I, g \rangle|^2 |I|^{-1} 1_I \right)^{\frac{1}{2}} Mf
\]

\[
\leq \| (\epsilon_I)_I \|_{\text{BMO}} \|Mf\|_p \|Sg\|_p \leq C_p \| (\epsilon_I)_I \|_{\text{BMO}} \|f\|_p .
\]

Here we have used boundedness of the Hardy Littlewood maximal operator in \(L^p\) and boundedness of the square function in \(L^{p'}\). The same calculation shows that the expression (??) converges in \(L^p\) regardless of the order of summation.

Vice versa, assume \(P_\epsilon\) is bounded in \(L^p\). Let \(J\) be any dyadic interval and let \(f = 1_J\). Then we have

\[
\left\| \sum_{I \subseteq J} |I|^{\frac{1}{2}}\epsilon_I h_I \right\|_p = \left\| \sum_{I \subseteq J} \epsilon_I \langle f, \chi_I \rangle h_I \right\|_p
\]

24
\[ \leq C_P \left\| \sum I \epsilon_I \langle f, \chi_I \rangle h_I \right\|_{L^p} \leq C_P \| f \|_p \leq C_P |J|^p \]

Here the passage from the first to the second line is easily seen from passing to the norm of the square function, which is equivalent to the norm of a function. This calculation and Lemma 8 show that \((\epsilon_I)_I\) is a BMO sequence.

If we formally apply \(P_\epsilon\) to the constant function \(1\), then we have

\[ P_\epsilon(1) = \sum I |I|^{\frac{1}{2}} \epsilon_I h_I . \]

Thus the condition in the previous Lemma can be described as \(P_\epsilon(1) \in \text{BMO}\). A variant of this condition gives the \(T(1)\)-theorem below its name.

By duality, we have that the adjoint operator \(P_\epsilon^*\) of \(P_\epsilon\) is bounded in \(L^p\) for \(1 < p < \infty\) if and only if \(\epsilon_I\) is a BMO sequence. Since we have

\[ \langle P_\epsilon f, g \rangle = \sum I \epsilon_I \langle f, \chi_I \rangle \langle h_I, g \rangle , \]

we obtain for the adjoint operator \(P_\epsilon^*\) of \(P_\epsilon\) formally the expression

\[ P_\epsilon^* f = \sum I \epsilon_I \langle f, h_I \rangle \chi_I , \tag{18} \]

which is a finite sum if \(f \in \mathcal{H}(\mathbb{R})\) and which converges weakly in \(L^p\) if \((\epsilon_I)_I\) is a BMO sequence and \(f \in L^p\). To see that (18) actually converges strongly in \(L^p\) regardless of the order of summation, observe that by Lebesgue’s dominated convergence theorem (7) converges strongly in some order of summation if

\[ P_\epsilon^* f = \sum I \epsilon_I |\langle f, h_I \rangle| \chi_I , \]

converges in \(L^p\) in that order of summation. But by Lebesgue’s monotone convergence theorem the latter converges strongly in \(L^p\) in any order of summation.

More generally, we have the following discrete \(T(1)\) theorem

**Theorem 1** Let \((\epsilon_I^{(j)})_{I \in \mathbb{I}}\) be bounded sequences of real numbers for \(j = 1, 2, 3\). Then the operator \(T\), originally defined on \(\mathcal{H}(\mathbb{R})\) by

\[ Tf = \sum I \epsilon_I^{(1)} \langle f, h_I \rangle h_I + \sum I \epsilon_I^{(2)} \langle f, \chi_I \rangle h_I + \sum I \epsilon_I^{(3)} \langle f, h_I \rangle \chi_I \]

is bounded in \(L^p\) for \(1 < p < \infty\) if \(T(1) \in \text{BMO}\) and \(T^*(1) \in \text{BMO}\).

Here of course the conditions \(T(1)\) and \(T^*(1)\) in BMO are to be interpreted in the sense that \((\epsilon_I^{(j)})_{I \in \mathbb{I}}\) and \((\epsilon_I^{(j)})_{I \in \mathbb{I}}\) are BMO sequences.
10 The continuous $T(1)$ theorem

10.1 The Theorem

Each topic in the discrete theory of Part I translates into a continuous counterpart more closely related to Fourier analysis. Rather than discussing the whole theory in the continuous case again, we shall focus on the continuous $T(1)$ theorem. This theorem was originally proved in 1984 and is one of the highlights of the theory of singular integral operators. We formulate the theorem in $\mathbb{R}^n$, but since we would like to focus on the ideas, we shall for simplicity prove the case $n = 1$ only.

A Calderon Zygmund kernel (with parameters $A > 0$ and $\gamma > 0$) $K$ is a measurable function on $\mathbb{R}^n \times \mathbb{R}^n$ which satisfies

$$|K(x, y)| \leq A \frac{1}{|x - y|^n}$$

for all $x \neq y$, for all $x, x', y$ such that $|x - x'| < |x - y|/2$, and

$$|K(x, y) - K(x', y)| \leq A \frac{|x - x'|^\gamma}{|x - y|^{n+\gamma}}$$

and

$$|K(x, y) - K(x, y')| \leq A \frac{|y - y'|^\gamma}{|x - y|^{n+\gamma}}$$

for all $x, y', y$ such that $|y - y'| < |x - y|/2$.

Observe that these conditions imply that $K$ is continuous away from the diagonal $x = y$, in fact it is Hölder continuous of degree $\gamma$. The Calderon Zygmund conditions become weaker as $\gamma$ approaches 0, with $\gamma = 0$ the conditions reduce to (??), which turns out to be weak by itself to give a reasonable boundedness theory.

To compare this with the discrete $T(1)$ theorem observe that the kernel

$$\sum_I \epsilon_I^{(1)} h_I(x) h_I(y) + \epsilon_I^{(2)} \chi_I(x) h_I(y) + \epsilon_I^{(3)} h_I(x) \chi_I(y)$$

satisfies the conditions

$$|K(x, y)| \leq A |I_{x,y}|^{-1}$$

for all positive $x \neq y$, where $I(x, y)$ is the smallest dyadic interval containing $x$ and $y$,

$$|K(x, y) - K(x', y)| = 0$$

for all pairwise distinct positive $x, x', y$ such that the smallest dyadic interval containing $x$ and $x'$ has smaller length than the smallest dyadic interval containing $x$ and $y$, and

$$|K(x, y) - K(x, y')| = 0$$

for all pairwise distinct positive $x, y', y$ such that the smallest dyadic interval containing $y$ and $y'$ has smaller length than the smallest dyadic interval containing $x$ and
\( y \); and similarly on the negative axis. These properties of (21) are easily seen, using that \( \epsilon_f^{(j)} \) are bounded.

Given a Calderon Zygmund kernel, we would like to define an operator \( T \) mapping \( \mathcal{S}(\mathbb{R}^n) \) to \( \mathcal{S}'(\mathbb{R}^n) \) by

\[
(T f, g) = \int_{\mathbb{R}^n} \int_{\mathbb{R}^n} K(x, y) f(y) g(x) \, dy \, dx .
\]

However, it is not clear how to make sense of this expression, because \( K \) is not an integrable function. We shall therefore not attempt to define \( T \) by (21). However, we observe that \( K \) is locally integrable away from the diagonal, therefore we make the following definition:

**Definition 1** An operator \( T : \mathcal{S}(\mathbb{R}^n) \to \mathcal{S}'(\mathbb{R}^n) \) is said to have a Calderon Zygmund kernel \( K \) if (21) holds for all compactly supported Schwartz functions \( f \) and \( g \) which have disjoint supports.

It is easy to see that if \( T \) has Calderon Zygmund kernel \( K \), then the adjoint operator \( T^* \) defined by

\[
\langle T^* f, g \rangle = \langle f, T g \rangle
\]

has the Calderon Zygmund kernel

\[
K^*(x, y) = \overline{K(y, x)} ,
\]

the Calderon Zygmund conditions for \( K^* \) being easily verified.

Observe that an operator can have at most one Calderon Zygmund kernel, because we can obtain the value \( K(x, y) \) as a limit of \( (T f, g) \) where the supports of \( f \) and \( g \) shrink to \( x \) and \( y \) respectively. However, several operators can have the same Calderon Zygmund kernel, e.g. for each \( x \in \mathbb{R}^n \) and each \( c \in \mathbb{R} \) the operator defined by \( (T f, g) = cf(x) g(x) \) has the kernel \( K = 0 \).

The last example also shows, that an operator \( T \) with a Calderon Zygmund kernel \( K \) is not necessarily bounded in \( L^2(\mathbb{R}^n) \). The \( T(1) \) theorem, which we are about to state, characterizes the operators with Calderon Zygmund kernels which are bounded in \( L^2(\mathbb{R}^n) \).

Recall the following notation:

\[
D^\alpha f(x) = \lambda^{-\frac{1}{p}} f(\lambda^{-1} x) \quad T_y f(x) = f(x - y) \quad D^\alpha f = (2\pi i)^{-|\alpha|} \partial_1^{\alpha_1} \cdots \partial_n^{\alpha_n} f \quad X^\beta f(x) = x_1^{\beta_1} \cdots x_n^{\beta_n} f(x) \quad \|f\|_{[N]} = \sup_{|\alpha|,|\beta| \leq N} \|D^\alpha X^\beta f\|_2
\]
Theorem 2 Let $T$ be a continuous operator from $\mathcal{S}(\mathbb{R}^n)$ to $\mathcal{S}'(\mathbb{R}^n)$ and assume $T$ has a Calderon-Zygmund kernel $K$. Then $T$ extends to a bounded operator from $L^2(\mathbb{R}^n)$ to itself if and only if there exist an $N > 0$ and an $A' > 0$ such that

(22) \[ \|T(T_x D_\lambda^2 f)\|_2 \leq A'\|f\|_{[N]} \]

(23) \[ \|T^*(T_x D_\lambda^2 f)\|_2 \leq A'\|f\|_{[N]} \]

for all $x \in \mathbb{R}^n$, $\lambda \in \mathbb{R}^+$, and $f \in \mathcal{S}(\mathbb{R}^n)$. More precisely, we have

\[ \|Tf\|_2 \leq C_N \max(A, A')\|f\| \]

for all $f \in \mathcal{S}(\mathbb{R})$, where $C_N$ depends only on $N$, and $A$ is the constant in the conditions on the Calderon-Zygmund kernel.

The necessity of the condition is immediately clear, because if $T$ is bounded then it follows that

\[ \|T(T_x D_\lambda^2 f)\|_2 \leq C\|f\|_2 \leq C\|f\|_{[N]} \]

and likewise for $T^*$. The proof of sufficiency of this condition will be done in the next few sections.

10.2 Identifying the part corresponding to $\sum I \epsilon_I h_I \otimes h_I$

We begin to prove boundedness of $T$ as in Theorem 2. For simplicity we discuss the one dimensional case only. Moreover, for simplicity of notation we shall not discuss the dependence of the constants on $A$, $A'$, and $N$.

First we observe that if $f$ is a compactly supported Schwartz function with mean zero, then $Tf$ is actually in $L^1$. By hypothesis of the theorem it is clear that $Tf \in L^2$. Let $B$ be a ball with radius larger than 1 around the origin of $\mathbb{R}$ such that the support of $f$ is contained in $B$. Then it suffices to show that $f$ restricted to the complement of $3B$ is a finite measure, i.e.,

\[ |(Tf, g)| \leq C\|g\|_\infty \]

for some constant $C$ and all $g \in \mathcal{S}(\mathbb{R})$ supported outside $2B$. Since $f$ and $g$ have disjoint support, we can write

\[ |(Tf, g)| = \left| \int \int K(x, y)f(y)g(x) \, dx \, dy \right| \]

Using the mean 0 property of $f$ this is the same as

\[ \left| \int \int (K(x, y) - K(x, 0))f(y)g(x) \, dx \, dy \right| \]

Since $|y - 0| < \frac{1}{2}|x - 0|$ on the support of $f(y)g(x)$, this is bounded by

\[ \int \int \frac{|y|^\gamma}{|x|^{1+\gamma}} |f(y)||g(x)| \, dx \, dy \]
\[
\leq C \int \frac{1}{|x|^{1+\gamma}} |g(x)| \, dx \\
\leq C \|g\|_{\infty} \int_{|x|}^\infty |x|^{-1-\gamma} \, dx \leq C \|g\|_{\infty}.
\]

This proves that \( Tf \in L^1 \) if \( f \) is compactly supported and has mean zero. By symmetry the same holds for \( T^* \). Hence we can take the mean of \( Tf \) and \( T^*f \) for such functions \( f \).

Our plan is to first prove boundedness of \( T \) under the additional assumption that all these means are zero, i.e.,

\[
\int Tf(x) \, dx = 0
\]

and

\[
\int T^*f(x) \, dx = 0
\]

for all compactly supported \( f \in \mathcal{S}(\mathbb{R}) \) with \( f(x) \, dx = 0 \). To motivate this assumption we discuss the meaning of this assumption in the discrete model. Assume we have \( T \) given by the kernel

\[
\sum_I \sum_I \epsilon_I h_I(x) h_I(y) + \epsilon^{(2)}_I \chi_I(x) h_I(y) + \epsilon^{(3)}_I h_I(x) \chi_I(y)
\]

In the discrete setting the natural ("smooth") function with compact support is a Haar function \( h_I \). Observe that

\[
\int Th_I(x) \, dx = \epsilon^{(3)}_I |I|^\frac{1}{2}
\]

\[
\int T^*h_I(x) \, dx = \epsilon^{(2)}_I |I|^\frac{1}{2}
\]

Thus the additional assumption in the discrete case is the same as saying that all \( \epsilon^{(2)}_I \) and \( \epsilon^{(3)}_I \) are 0. In this sense we are dealing with the \( \sum_I \epsilon^{(1)}_I h_I \otimes h_I \)-part only.

The next step is to decompose the operator \( T \) similarly to the decomposition in the discrete case. Pick a Schwartz function \( \phi \) supported in the unit ball \( B_1(0) \) with \( \hat{\phi}(0) = 1 \). Define \( \phi_n \) and \( \psi_n \) by

\[
\hat{\phi}_j = \mathbb{D}_{2^n} \hat{\phi},
\]

\[
\psi_j = \phi_j - \phi_{j-1}.
\]

Obviously \( \hat{\phi}_n(0) = 1 \) and \( \hat{\psi}_j(0) = 0 \) for all \( j \).

It is easy to see that for each \( f \in \mathcal{S}(\mathbb{R}) \)

\[
\lim_{j \to \infty} f \ast \phi_j = f
\]

\[
\lim_{j \to \infty} f \ast \phi_j = 0
\]

\[
\lim_{j \to \infty} T(f \ast \phi_j) \ast \phi_j = Tf
\]

29
\[
\lim_{j \to -\infty} T(f * \phi_j) * \phi_j = 0
\]

Thus we can write \( T \) as a telescoping series

\[
T = \sum_{j=-\infty}^{\infty} T_j
\]

where \( T_j \) is defined by

\[
T_j f = T(f * \phi_j) * \phi_j - T(f * \phi_{j-1}) * \phi_{j-1}
\]

Convolution with \( \phi_j \) is a smoothing operation at scale \( 2^{-j} \). In the discrete model this corresponds to replacing a function \( f \) on each dyadic interval of length \( 2^{-j} \) by its average:

\[
f \to \sum_{|I| > 2^{-j}} \langle f, h_I \rangle h_I
\]

Thus the operator \( f \to T(f * \phi_j) * \phi_j \) in the case of (??) with vanishing paraproducts is given by

\[
f \to \sum_{|I| > 2^{-j}} \epsilon^{(1)}_{(I)} \langle f, h_I \rangle h_I
\]

The analogue of the operator \( T_j \) is then given by

\[
f \to \sum_{|I| = 2^{-j}} \epsilon^{(1)}_{(I)} \langle f, h_I \rangle h_I
\]

which is taking a single scale of \( T \).

We study the operators \( T_j \). First observe that we can write for \( T_j f \)

\[
T(f * \phi_j) * \phi_j - T(f * \phi_j) * \phi_{j-1} + T(f * \phi_j) * \phi_{j-1} - T(f * \phi_{j-1}) * \phi_{j-1}
\]

\[
= T(f * \phi_j) * \psi_j + T(f * \psi_j) * \phi_{j-1}
\]

Since both pieces are similar we will only consider

\[
T^{(1)}_j = T(f * \phi_j) * \psi_j
\]

Our strategy now is as follows. We will prove in the next section that the operators \( T_j \) are almost orthogonal, i.e.,

\[
\|T_j T^\ast_j\| \leq C 2^{-\gamma' |i-j|}
\]

\[
\|T^\ast_j T_j\| \leq C 2^{-\gamma' |i-j|}
\]

for some \( \gamma' < \gamma \). (In the discrete model they actually are pairwise orthogonal). Then we will prove a lemma by Cotlar and Stein which says that almost orthogonality of the \( T_j \) implies that \( \sum_j T_j \) is a bounded operator in \( L^2 \).
10.3 Estimates on $T_i T_j^*$ and $T_i^* T_j$

First we prove an easy general lemma, which will be applied to the operators $T_i^* T_j$ and $T_i T_j^*$.

**Lemma 11** Let $A > 0$ and let $K$ be a bounded continuous (weaker assumptions would do) function on $\mathbb{R}^2$ such that for all $x, y \in \mathbb{R}$ we have

$$\int |K(t, y)| dt \leq A ,$$

$$\int |K(x, t)| dt \leq A .$$

Then the operator $S : \mathcal{S}(\mathbb{R}) \to \mathcal{S}'(\mathbb{R})$ defined by

$$(Sf, g) = \int \int K(x, y) f(y) g(x) \, dy \, dx$$

extends to a bounded operator from $L^2$ to $L^2$. More precisely it satisfies

$$|(Sf, g)| \leq 2A \|f\|_2 \|g\|_2 .$$

**Proof** By linearity it suffices to prove this for $\|f\|_2 = \|g\|_2 = 1$. We observe that

$$|f(y) g(x)| \leq |f(y)|^2 + |g(x)|^2 .$$

Hence

$$|(Sf, g)| = \left| \int \int K(x, y) f(y) g(x) \, dy \, dx \right|$$

$$\leq \int \int |K(x, y)||f(y)|^2 \, dxdy + \int \int |K(x, y)||g(x)|^2 \, dxdy$$

$$\leq A \int |f(y)|^2 \, dy + A \int |g(x)|^2 \, dx \leq 2A$$

This completes the proof. ■

We return to the discussion of the operators $T_j$.

Recall the formula

$$\Lambda \ast f(x) = (\Lambda, \tilde{f})$$

where $\Lambda \in \mathcal{S}'(\mathbb{R})$, $f \in \mathcal{S}(\mathbb{R})$, and $\tilde{f}(x) = f(-x)$. Also, for $f, g \in \mathcal{S}(\mathbb{R})$ we have the formula

$$f \ast g = \int f(t) T_j g \, dt$$

where the right hand side is a vector valued integral, which can be interpreted as limit of the Riemann sums

$$\frac{1}{K} \sum_{k=-K^2}^{K^2} f(k/K) T_j^k g$$

31
as $K \to \infty$, with convergence in $S(\mathbb{R})$. Since $T$ is continuous form $S(\mathbb{R})$ to $S(\mathbb{R}')$, we obtain

$$T(f * \phi_j) * \psi_j(x) = \left( T(f * \phi_j), T_x \tilde{\psi} \right)$$

$$= \left( T \left( \int f(t)T_t \phi_j \, dt \right), T_x \tilde{\psi} \right)$$

$$= \int f(t) \left( T(T_t \phi_j, T_x \tilde{\psi}_j) \right) dt$$

Thus the operator $T_j$ is given by a smooth kernel

$$K_j(x, t) = \left( T(T_t \phi_j, T_x \tilde{\psi}_j) \right) dt$$

By hypothesis (19) of the theorem we have

$$|K_j(x, t)| \leq 2^j \| \phi \|_{[N]} \| \psi \|_2 \leq C 2^j .$$

If $|x - t| > 2^{-j+2}$, then $T_t \phi_j$ and $T_x \tilde{\psi}_j$ have disjoint support and we have

$$|K_j(x, t)| \leq \left| \int \int K(x', t') \phi_j(t' - t) \tilde{\psi}_j(x' - x) \, dt' \, dx' \right|$$

$$= \left| \int \int (K(x', t') - K(x, t')) \phi_j(t' - t) \tilde{\psi}_j(x' - x) \, dt' \, dx' \right|$$

$$\leq C \int \int \frac{|x - x'|^\gamma}{|x' - t'|^{1+\gamma}} |\phi_j(t' - t)||\tilde{\psi}_j(x' - x)| \, dt' \, dx'$$

$$\leq C \| \phi \|_1 |x - t|^{-(1+\gamma)} \int \int |x - x'|^\gamma |\tilde{\psi}_j(x' - x)| \, dt' \, dx'$$

$$\leq C \| \phi \|_1 \| \psi \|_1 |x - t|^{-(1+\gamma)} (2^j)^\gamma$$

Putting both estimates together we obtain

$$|K(x, t)| \leq C 2^j \min \left( 1, \left( \frac{|x - t|}{2^{-j}} \right)^{1-\gamma} \right) .$$

Similarly, we obtain

$$|D_1^\alpha D_2^\beta K(x, t)| = \left| \left( T(D_1^\alpha T_t \phi_j), D_2^\beta T_x \tilde{\psi}_j \right) \right|$$

$$\leq C 2^{j(1+|\alpha|+|\beta|)} \min \left( 1, \left( \frac{|x - t|}{2^{-j}} \right)^{1-\gamma} \right) .$$

The additional mean zero assumptions on $T$ and $T^*$ yield

$$\int K_j(x, y) \, dx = 0$$

(25)

$$\int K_j(x, y) \, dy = 0$$

(26)
Consider first (??). It is equivalent to

\[ \int \int K_j(x, y)f(y) \, dx \, dy = 0 \]

which is the same as

\[ \int T_j f(x) \, dx = 0 \]

However,

\[ T_j f = T(f \ast \phi_j) \ast \psi_j \]

If \( T_j f(x) \) was integrable, this would already imply (??) because \( \psi_j \) has mean zero. Let \( B \) be a large ball centered at the origin such that \( f \ast \phi_j \) is supported in \( B \). We consider \( T(f \ast \phi) \) separately on \( 2B \) and the complement of \( 2B \). On \( 2B \) it is in \( L^1 \) because it is locally in \( L^2 \). Therefore we can apply the above argument. For \( x \in 2B^c \) we have that \( T(f \ast \phi_j)(x) \) is given by

\[ \int K(x, y)T(f \ast \phi_j)(y) \, dy 1_{2B^c}(x) \]

Convolving this with \( \psi_j \) and taking the mean gives

\[ \int \int \int K(x, y)T(f \ast \phi_j)(y)1_{2B^c}(x)\phi(t - x) \, dy \, dt \, dx , \]

\[ = \int \int [K(x, y) - K(x, 0)]T(f \ast \phi_j)(y)1_{2B^c}(x)\phi(t - x) \, dy \, dt \, dx . \]

Now the integrand is absolutely integrable, and we can use Fubini to integrate first in \( x \) to see that this is equal to 0. (This is the point of throwing in \( K(x, 0) \): before that we couldn’t apply Fubini.) This proves (??).

Equation (??) is equivalent to

\[ \int T_j^* f(x) \, dx = 0 \]

We have

\[ T_j^* f = T^*(f \ast \overline{\psi_j}) \ast \phi_j , \]

which has mean zero by the special assumption on \( T^* \) because \( f \ast \overline{\psi_j} \) has mean zero.

Now we have to calculate \( \|T_i^* T_j\| \) and \( \|T_i T_j^*\| \). By symmetry it suffices to calculate the first norm only and assume \( i \geq j \).

The kernel of \( T_i^* T_j \) is given by

\[ K_{i,j}(x, y) = \int \overline{K_i(t, x)} K_j(t, y) \, dt \]

By the cancellation condition (??) this is equal to

\[ K_{i,j}(x, y) = \int \overline{K_i(t, x)}[K_j(t, y) - K_j(x, y)] \, dt \]
First we consider this integral on the region $E$ of all $t$ such that
\[ |t - x| \leq 2^{-i} 2^{\gamma(i-j)}. \]
We have
\[
\left| \int_E \overline{K_i(t, x)} [K_j(t, y) - K_j(x, y)] \, dt \right| \\
\leq \left\| K_i(x, \cdot) \right\|_1 |E| \sup_{t \in E} |\partial_t K_j(t, y)| \\
\leq C 2^{-i} 2^{\gamma(i-j)} 2^{2j} \min \left( 1, \left( \frac{|x - y|}{2^{-j}} \right)^{1+\gamma} \right)
\]
In the last line we could replace the supremum over $t$ by evaluation at $x$ (an loose at most a factor of 2) because $|x - t| \leq 2^{-j}$. Now we consider the integral on the complement of $E$ intersected with the set $F$ of all $t$ such that $2|x - t| < |x - y|$. There we have
\[
\left| \int_{E^c \cap F^c} \overline{K_i(t, x)} [K_j(t, y) - K_j(x, y)] \, dt \right| \\
\leq \left\| K_i(\cdot, y) \right\|_{L^1(E^c)} \sup_{t \in E^c} |K_j(t, x)| \\
\leq C 2^{-\gamma(i-j)} \min \left( 1, \left( \frac{|x - y|}{2^{-j}} \right)^{1+\gamma} \right)
\]
In the last line we have used that $|x - y|$ and $|t - y|$ are of comparable size within a factor of 2. Finally, we consider the integral on $E^c \cap F^c$. There we have
\[
\left| \int_{E^c \cap F^c} \overline{K_i(t, x)} [K_j(t, y) - K_j(x, y)] \, dt \right| \\
\leq \left\| K_j(\cdot, y) \right\|_{L^1(E^c \cap F^c)} \sup_{t \in E^c \cap F^c} \left\| K_i(\cdot, x) \right\|_1 \\
\leq C 2^{i} \sup_{t \in E^c \cap F^c} \min \left( 1, \left( \frac{|x - t|}{2^{-i}} \right)^{1+\gamma} \right) \\
\leq C 2^{i} 2^{-\gamma(i-j)} \min \left( 1, \left( \frac{|x - y|}{2^{-j}} \right)^{1+\gamma} \right)
\]
In the last line we have used that for each $t \in E^c \cap F^c$ the minimum in the previous line is attained by the element
\[
\left( \frac{|x - t|}{2^{-i}} \right)^{1+\gamma} \leq 2^{-(1+\gamma)(i-j)} \left( \frac{|x - y|}{2^{-j}} \right)^{1+\gamma}
\]
These three estimates together give
\[
|K_{i,j}(x, y)| \leq C 2^{i} 2^{-\gamma''(i-j)} \min \left( 1, \left( \frac{|x - y|}{2^{-j}} \right)^{1+\gamma} \right)
\]
for some $\gamma'' > 0$.

By Lemma (??) this easily implies $\|T_i^*T_j\| \leq 2^{-\gamma''|i-j|}$, which we had aimed to prove.
10.4 The Cotlar-Stein Lemma

The Cotlar-Stein lemma is a lemma on bounded operators on a Hilbert space. We will write \( f \) for an element of this Hilbert space and \( \|f\|_2 \) for its norm. The norm of a bounded operator \( T \) form the Hilbert space to itself will be denoted by \( \|T\| \).

**Lemma 12** Let \( (T_j)_{j=1}^f \) be a finite set of bounded linear operators on a Hilbert space. Assume that for each \( j \) we have

\[
\sum_i \left\| T_j T_i^* \right\|^\frac{1}{2} \leq C
\]

\[
\sum_i \left\| T_j^* T_i \right\|^\frac{1}{2} \leq C
\]

Then

\[
\left\| \sum_j T_j \right\| \leq C
\]

**Proof**

First we recall that the operator norm of an operator \( T \) on a Hilbert space satisfies

\[
\|T\| = \|T^*\|
\]

and

\[
\|T\|^2 = \|T^* T\|.
\]

The first statement follows as

\[
\|T\|^2 = \sup_{\|f\|_2=1} \|T f\|_2 = \sup_{\|f\|_2,\|g\|_2=1} |\langle T f, g \rangle|
\]

\[
= \sup_{\|f\|_2,\|g\|_2=1} |\langle f, T^* g \rangle| = \ldots = \|T^*\|
\]

For the second statement we observe

\[
\|T\|^2 = \sup_{\|f\|_2=1} \|T f\|_2^2 = \sup_{f} \langle T f, T f \rangle = \sup_{f} \langle T^* T f, f \rangle \leq \sup_{f} \|T^* T f\|_2 = \|T^* T\|
\]

and on the other hand

\[
\|T^* T\| \leq \|T\| \|T^*\| \leq \|T\|^2.
\]

We make a few more observations to motivate the proof of Cotlar-Stein. We trivially have

\[
\| \sum_j T_j \| \leq \sum_j \| T_j \|
\]

if we assume \( T^*_i T_j = 0 \) for all \( i \neq j \) we have

\[
\| \sum_j T_j \|^2 = \| \sum_i \sum_j T^*_j T_i \| = \| \sum_j T^*_j T_j \| = \sum_j \| T_j \|^2.
\]
thus we can replace the sum in (??) by a square sum, which is clearly better. We observe that the same would be true if we had assumed $T_j^*T_i = 0$ for all $j \neq i$, because then we could run this argument on $\sum_j T_j^*$ and the invoke (??).

If we assume both $T_j^*T_i = 0$ and $T_jT_i^* = 0$ for all $i \neq j$, then we can continue to estimate higher powers: For self adjoint operators $T$ equation (??) gives $\|H^2\| = \|H\|^2$, which can be iterated to give

$$\|H^n\| = \|H\|^n$$

for $n$ some power of 2. Since $T^*T$ is self adjoint for any operator $T$, we obtain

$$\left\| \sum_j T_j^*T_j \right\|^n = \left\| \sum_{j_1,j_2,\ldots,j_n} T_{j_1}^*T_{j_2}^*T_{j_1}T_{j_2} \cdots T_{j_n}^*T_{j_n} \right\|$$

$$= \| \sum_j (T_j^*T_j)^n \| \leq \sum_j \| T_j^*T_j \|^n$$

Thus we can replace the sum in (??) by an $2n$-sum, which in the limit becomes a supremum:

$$\left\| \sum_j T_j \right\| \leq \sup_j \| T_j \| ,$$

which is clearly the best one can do.

We return to the proof of Cotlar Stein. We have for $n$ any power of 2:

$$\left\| \sum_j T_j \right\|^{2n} = \left\| \sum_{j_1,j_2,\ldots,j_{2n}} T_{j_1}^*T_{j_2}^*T_{j_1}T_{j_2} \cdots T_{j_{2n-1}}^*T_{j_{2n}} \right\|$$

This is bounded by either one of the two following quantities

$$\sum_{j_1,j_2,\ldots,j_{2n}} \| T_{j_1}^*T_{j_2} \| \| T_{j_2}^*T_{j_3} \| \cdots \| T_{j_{2n-1}}^*T_{j_{2n}} \|$$

$$\sum_{j_1,j_2,\ldots,j_{2n}} \| T_{j_1} \| \| T_{j_2} \| \| T_{j_3} \| \cdots \| T_{j_{2n}} \|$$

For each tuple $j_1,\ldots,j_{2n}$ we can take the geometric mean of the two terms, which gives

$$\left\| \sum_j T_j \right\|^{2n} \leq \sum_{j_1,j_2,\ldots,j_{2n}} \left( \| T_{j_1}^*T_{j_2} \| \| T_{j_2}T_{j_3} \| \cdots \| T_{j_{2n-1}}^*T_{j_{2n}} \| \right)^{\frac{1}{2}}$$

Now we unravel the sum and use the assumptions of the lemma:

$$\leq C^{\frac{1}{2}} \sum_{j_2,\ldots,j_{2n}} \left( \| T_{j_2}T_{j_3} \| \cdots \| T_{j_{2n-1}}^*T_{j_{2n}} \| \right)^{\frac{1}{2}}$$

$$\leq C^{\frac{1}{2}} \sum_{j_3,\ldots,j_{2n}} \left( \| T_{j_3}T_{j_4} \| \cdots \| T_{j_{2n-1}}^*T_{j_{2n}} \| \right)^{\frac{1}{2}}$$

36
\[ \leq \cdots \leq C^{\frac{4n-1}{2n}} \sum_{j \leq n} \| T_{j} \|^{\frac{1}{2}} \leq JC^{2n} \]

Taking roots gives
\[ \| \sum_{j} T_{j} \| \leq C(J)^{\frac{1}{2n}} \]

which proves the lemma as \( n \) tends to \( \infty \). ■

10.5 The paraproducts

We have proved the \( T(1) \) theorem under the additional assumptions

\[ \int T f(x) \, dx = 0 \]
\[ \int T^* f(x) \, dx = 0 \]

for all compactly supported \( f \) with \( \int f(x) \, dx = 0 \). Now we remove these additional assumptions. Let \( T \) be as in the \( T(1) \) theorem. It suffices to construct two operators \( P_{1} \) and \( P_{2} \) which are bounded in \( L^{2} \), have Calderon Zygmund kernels, and satisfy

\[ \int P f(x) \, dx = \int T f(x) \, dx \]
\[ \int P^* f(x) \, dx = 0 \]
\[ \int Q f(x) \, dx = 0 \]
\[ \int Q^* f(x) \, dx = \int T^* f(x) \, dx \]

Namely, then \( T - P - Q \) has a Calderon Zygmund kernel, satisfies the assumptions of the \( T(1) \) theorem, and the additional cancellation assumptions (??) and (??). Thus \( T - P - Q \) is bounded in \( L^{2} \) by what we have seen before. Since \( P \) and \( Q \) are bounded, so is \( T \), which had to be shown.

There are many ways to construct such operators \( P \) and \( Q \). Given the discrete theory, this becomes particularly easy if one assumes the existence of a compactly supported sufficiently regular wavelet. We shall do so and prove the existence of such wavelets later. (It turns out that the existence of such wavelets takes some work, which in total makes our approach not as economic as it might appear at first glance. However, since studying wavelets is of its own interest, we choose this approach.)

Thus we assume that there is a compactly supported, \( N \) times continuously differentiable function (the \( N \) from the \( T(1) \) theorem, which we can assume to be larger than 1) \( \psi \) with mean 0, such that, if we define for each dyadic interval \( I = [2^k n, 2^k (n + 1)] \) the function \( \psi_I \) to be
\[ \psi_I = D_{2k}^2 T_n \psi \]
we have
\begin{equation}
\sum_I \langle f, \psi_I \rangle \psi_I = f
\end{equation}
for all \( f \in L^2(\mathbb{R}) \). Observe that the collection \( \psi_I \) was an orthonormal basis of \( L^2(\mathbb{R}) \) if \( \| \psi \| = 1 \); however, to simplify the later task of constructing \( \psi \) we shall not make this assumption.

Let \( \phi \) be a \( C^\infty \) function supported in \([0,1]\) with mean 1, and define \( \phi_I \) in analogy to \( \psi_I \).

By symmetry we shall only discuss \( P \). Define for \( f \in \mathcal{S}(\mathbb{R}) \):
\[
P f = \sum_I |I|^{-\frac{1}{2}} \langle f, \psi_I \rangle \varepsilon_I \phi_I
\]
where
\[
\varepsilon_I = \int T \phi_I(x) \, dx
\]
Assume for now that the sequence \( (\varepsilon_I)_I \) is a BMO sequence, we will prove this fact later. Then we have for every \( g \in \mathcal{S}(\mathbb{R}) \):
\[
|\langle Pf, g \rangle| = \left| \sum_I \langle f, \psi_I \rangle |I|^{-\frac{1}{2}} \langle \phi_I, g \rangle \right|
\leq \| \varepsilon_I \|_{\text{BMO}} \left\| \left( \sum_I \left| \sum_I \langle f, \psi_I \rangle \langle \phi_I, g \rangle \right|^2 |I|^{-1} \right)^{\frac{1}{2}} \right\|_1
\leq C \| \varepsilon_I \| \left( \sum_I \left| \langle f, \psi_I \rangle \right|^2 \right)^{\frac{1}{2}} \| Mg \|_2
\leq C \| \varepsilon_I \| \| f \|_2 \| g \|_2
\]
Hence \( P \) extends to a bounded operator on \( L^2 \). In this calculation we have used that \( \phi_I \) is dominated by a multiple of the characteristic function of \( I \) and therefore we can estimate \( \langle g, \phi_I \rangle \) by the Hardy Littlewood maximal function \( Mg \) of \( g \). The above calculation also justifies the infinite sum in the definition of \( P \).

We continue to assume that \( \varepsilon_I \) is a BMO sequence and therefore \( |I|^{-\frac{1}{2}} \varepsilon_I \leq C \) for all \( I \). We have for the kernel of \( P \) away from the diagonal \( x = y \):
\begin{equation}
K(x, y) = \sum_I |I|^{-\frac{1}{2}} \varepsilon_I \overline{\psi_I(y)} \phi_I(x)
\end{equation}
Let \( B \) be a large number so that the support of \( \psi \) is contained in \( -B/2, B/2 \). Then it is easy to see that the the support of \( \psi_I \) is contained in \( BI \), where \( BI \) denotes the interval with the same center as \( I \) and length \( B|I| \). For each \( I \) with \( 2B|I| < |x-y| \) the corresponding term in the sum (???) vanishes because either \( x \) is not in the support of
\( \phi_I \) or \( y \) is not in the support of \( \psi_I \). Moreover, for each \( k \) there is at most 1 intervals \( I \) of length \( 2^k \) such that \( \phi_I(x) \) is nonzero. Hence we easily see
\[
|K(x, y)| \leq C \sum_{k: 2^k > (2B)^{-1}|x-y|} 2^{-k} \leq C|x-y|^{-1}. 
\]
Moreover the same argument gives
\[
|\partial_z K(x, y)| = \sum_I |I|^{-\frac{1}{2}} \epsilon_I \psi_I(y) \phi_I(x) \leq C|B| \sum_{k: 2^k > (2B)^{-1}|x-y|} 2^{-2k} \leq C|x-y|^{-2}. 
\]
Likewise we obtain an estimate for \( \partial_y K \). By the fundamental theorem of calculus this proves that \( K \) is a Calderon Zygmund kernel.

We now prove that \( \epsilon_I \) is a BMO sequence.

Let \( \varphi \) be a compactly supported function which is constant equal to 1 on some interval around the origin. Let \( J \) be any dyadic interval and consider \( x_0, \lambda_0 \) so that \( \lambda_0 < C|J| \) and \( D_0^\infty T_{x_0} \varphi \) is constant on \( 4BJ \).

Then we have
\[
\sum_{I \subseteq J} \left| \int I \psi_I(x) \, dx \right|^2 \leq C \sum_{I} \left| \langle T \psi_I(x), D_0^\infty T_{x_0} \varphi \rangle \right|^2 + C \sum_{I \subseteq J} \left| \int_{AB \cap J} T \psi_I(x) \, dx \right|^2 
\]
By the reproducing formula (36) the first term on the right hand side is bounded by
\[
C \| T^* D_0^\infty T_{x_0} \varphi \|_2 \leq C \lambda \leq C|J| 
\]
Here we have used the full strength of the assumption in the \( T(1) \) theorem. For the second term we consider each \( I \) separately:
\[
(36) \quad \left| \int_{AB \cap J} T \psi_I(x) \, dx \right| 
\leq \left| \int_{AB \cap J} \int_{y} (K(x, y) - K(x, c(I))) \psi_I(y) \, dy \, dx \right| 
\leq \left| \int_{AB \cap J} \int_{y} |I^n| |x - c(I)|^{-1-\gamma} \psi_I(y) \, dy \, dx \right| 
\leq |I|^{\frac{1}{2}} \left| \int_{AB \cap J} |I^n| |x - c(I)|^{-1-\gamma} \, dx \right| 
\leq |I|^{\frac{1}{2}} (|I|/|J|)^\gamma 
\]
For the square sum of these terms over all \( I \subset J \) we obtain
\[
\sum_{I \subset J} \left| \int_{2B \cap J} T \psi_I(x) \, dx \right|^2 
\]
$$\leq C \sum_{k > 0} \sum_{J \subset |I| = 2^{-k}|J|} |I|(|I|/|J|)^{2^\gamma}$$

$$\leq C \sum_{k > 0} |J|2^{-2^\gamma k} \leq C|J| .$$

Thus we have proved that

$$\sum_{I \subset J} |\epsilon_I|^2 \leq C|J|$$

for each dyadic interval $J$. This proves that $\epsilon_I$ is a BMO sequence.

It remains to prove that $P$ satisfies (3.16) and (3.17). Let $f$ be a compactly supported smooth function on with mean zero. Since $P$ satisfies the assumptions of the $T(1)$ theorem, the function $Pf$ is integrable.

We observe that

$$\int Pf(x) = \int \sum_{I} |I|^{-\frac{1}{2}} \epsilon_I \langle f, \psi_I \rangle \phi(x) \, dx$$

$$= \sum_I \epsilon_I \langle f, \psi_I \rangle .$$

To justify this calculation, we need to show that the right hand side converges absolutely, which follows from the easy observation that $\langle f, \psi_I \rangle$ is an $H^1$ sequence because $\epsilon_I$ is a BMO sequence. Let $\varphi$ be as above. We claim that

$$\sum_I \epsilon_I \langle f, \psi_I \rangle = \lim_{\lambda \to \infty} \sum_I \langle f, \psi_I \rangle \langle T\psi_I, D^\infty \varphi \rangle .$$

To prove this claim let $J = [-2^k, 2^k]$ be an interval around the origin that contains the support of $f$. Let $c$ be a small constant so that $\varphi$ is constant 1 on $[-c, c]$ and assume $\lambda$ satisfies $c\lambda > 2^{k+1}$. Then we have

$$\left| \sum_I \epsilon_I \langle f, \psi_I \rangle - \sum_I \langle f, \psi_I \rangle \langle T\psi_I, D^\infty \varphi \rangle \right|$$

$$\leq \left| \sum_I \langle f, \psi_I \rangle \int_{[-c\lambda, c\lambda]} T\psi_I(x) \, dx \right|$$

We split the sum into those $I$ with $I \subset J$ and those $I$ with $|I| \geq |J|$ and $I \cap J \neq \emptyset$. The first part can be estimated by the calculations done in (3.16) by

$$\leq C \left| \sum_{I \subset J} \langle f, \psi_I \rangle |I|^\frac{1}{2}(|I|/\lambda)^\gamma \right|$$

$$\leq C \sum_{I \subset J} \|f\|_\infty |I|(|I|/\lambda)^\gamma$$

$$\leq C \|f\|_\infty |J|(|J|/\lambda)^\gamma$$
The second part can be estimated by

\[
\sum_{I:|I| \geq |J|, I \cap J \neq \emptyset} |\langle f, \psi_I \rangle| \|T \psi_I \|_1
\]

Observe that if \( F \) is a compactly supported function with \( F' = f \) then

\[
\langle f, \psi_I \rangle = -\langle F, \psi'_I \rangle \leq |I|^{-\frac{3}{2}} \|F\|_1 \ .
\]

Moreover,

\[
\|T \psi_I \|_1 \leq \|T \psi_I \|_{L^1(AB)} + \|T \psi_I \|_{L^1(AB)'}
\]

\[
\leq C |I|^{-\frac{1}{2}} \|T \psi_I \|_2 + C |I|^{\frac{1}{2}} \leq C |I|^{\frac{1}{2}} \ .
\]

Hence (??) can be estimated by

\[
\sum_{I:|I| \geq |J|, I \cap J \neq \emptyset} C |I|^{-1} \leq C |J|^{-1}
\]

Letting \(|J|\) and \(\lambda / |J|\) tend to \(\infty\) proves the claim. Thus we have

\[
\int P f(x) \, dx = \lim_{\lambda \to \infty} \sum_I \langle f, \psi_I \rangle \langle T \psi_I, D^\infty_\lambda \varphi \rangle \ .
\]

\[
= \lim_{\lambda \to \infty} \sum_I \langle f, \psi_I \rangle \langle \psi_I, T^* D^\infty_\lambda \varphi \rangle \ .
\]

\[
= \lim_{\lambda \to \infty} \left( \sum_I \langle f, \psi_I \rangle \psi_I, T^* D^\infty_\lambda \varphi \right) \ .
\]

\[
= \lim_{\lambda \to \infty} \langle f, T^* D^\infty_\lambda \varphi \rangle \ .
\]

\[
= \int T f(x) \, dx \ .
\]

This proves (??).

It remains to discuss \( P^* \). Let again \( J = [-2^{k_0}, 2^{k_0}] \) contain the support of \( f \). Let \( \lambda \) satisfy \( c\lambda > B2^{k_0+1} \). Then

\[
\langle \int P^* f, D^\infty_\lambda \varphi \rangle = \sum_I |I|^{-\frac{1}{2}} \epsilon_I \langle f, \phi_I \rangle \langle \psi_I, D^\infty_\lambda \varphi \rangle
\]

\[
\langle \int P^* f, D^\infty_\lambda \varphi \rangle = \sum_{I:|I| > |J|, I \cap J \neq \emptyset} |I|^{-\frac{1}{2}} \epsilon_I \langle f, \phi_I \rangle \langle \psi_I, D^\infty_\lambda \varphi \rangle
\]

The last reduction follows because if \( I \cap J = \emptyset \) then \( \langle f, \phi_I \rangle = 0 \) and if \( |I| < |J| \) and \( I \subset J \) then \( BI \) is contained in \([-c\lambda, c\lambda]\) and therefore \( \langle \psi_I, D^\infty_\lambda \varphi \rangle = 0 \). However, similarly to before,

\[
\langle f, \phi_I \rangle \leq C |I|^{-\frac{3}{2}}
\]

\[
\langle \psi_I, D^\infty_\lambda \varphi \rangle \leq |I|^{\frac{3}{2}} \lambda^{-1}
\]
and therfore
\[
\sum_{I:|I|>|J|, I \cap J \neq \emptyset} |I|^{-\frac{1}{2}} \epsilon_I \langle f, \phi_I \rangle \langle \psi_I, D^\infty_x \varphi \rangle \\
\leq \sum_{I:|I|>|J|, I \cap J \neq \emptyset} |I|^{-\frac{1}{2}} \lambda^{-1} \leq |J|^{-\frac{1}{2}} \lambda^{-1}
\]
This tends to 0 as \( \lambda \) tends to \( \infty \), and thus proves

\[
\int P^sf(x) \, dx = 0 .
\]

This completes the discussion of the paraproducts and therefore the proof of the \( T(1) \) theorem.

## 11 Wavelets

### 11.1 The scaling function

Let \( \psi \) be a smooth compactly supported function with mean zero. We fix the notation that for every dyadic interval \( I = [2^k n, 2^k (n + 1)) \) we have

\[
\psi_I = T_n D_{2^k}^2 \psi .
\]

Then an easy consequence of the \( T(1) \) theorem is that the operator

\[
Tf = \sum_I \langle f, \psi_I \rangle \psi_I
\]

is bounded in \( L^2 \). One immediately observes that one can relax the assumptions on \( \psi \) quite a bit, for example \( \psi \in \mathcal{S}(\mathbb{R}) \) or \( \psi \) compactly supported and continuously differentiable would suffice.

Of course if one wants that \( T \) is the identity operator, as we did in the proof of the \( T(1) \) theorem, one has to impose stricter conditions on \( \psi \). Such a \( \psi \) is called a wavelet. In the following sections we will study the existence and construction of wavelets. Naturally this theory has a bit more of an algebraic flavor, because one is interested in the algebraic identity that \( T \) as above is the identity operator.

The function \( \psi \) and its siblings \( \psi_I \) we are looking for should resemble the Haar functions \( h_I \). It turns out, that the theory becomes easier and somewhat more natural if one constructs parallel a function \( \phi \) and siblings \( \phi_I \) which take the role of the characteristic functions \( \chi_I \). In fact we shall look at \( \phi_I \) first.

We shall work entirely in the Hilbert space \( L^2(\mathbb{R}) \). A function \( \phi \) is called scaling function, if

1. For all dyadic intervals \( I \) and \( J \) of the same length with \( I \neq J \) we have

\[
\langle \phi_I, \phi_J \rangle = 0
\]
2. The function $\phi$ is in the closed linear span of all $\phi_I$ with $|I| = 1/2$. (Then an analog statement holds for all $\phi_I$.)

3. The functions $\phi_I$ are a complete set in $L^2(\mathbb{R})$. Define $V_k$ to be the closed linear span of $\{ \phi_I : |I| \geq 2^k \}$, then the intersection of all $V_k$ is empty.

The spaces $V_k$ in this definition are sometimes said to form a multiresolution analysis.

At this stage of our discussion it is still not completely clear how to obtain scaling functions other than the Haar function. We postpone this point and first discuss how the scaling function leads to a wavelet.

From the analogy to the Haar system, it is plausible to look for wavelets in the orthogonal complement $W_0$ of $V_0$ inside $V_{-1}$. We shall first find a nice characterisation of such functions.

Every function in $V_{-1}$ is given as a linear combination

$$f = \sum_{|I|=1/2} \epsilon_I \phi_I$$

for some square summable sequence $\epsilon_I$. It will be useful to take the Fourier transform as follows

$$\hat{f} = \mathcal{F}\left( \sum_n \epsilon_{n/2,(n+1)/2} T_{n/2} D_{1/2}^2 \phi \right) = \sum_n \epsilon_{n/2,(n+1)/2} M_{n/2} D_{2}^2 \hat{\phi} = m_f(\xi) D_{2}^2 \hat{\phi} ,$$

where $m_f$ is the Fourier transform of $\epsilon_I$ in the sense

$$m_f(\xi) = \sum_n \epsilon_{n/2,(n+1)/2} e^{2\pi i (n/2) \xi}.$$

Observe that $m_f$ is periodic with period 2. The map $F : f \rightarrow m_f$ is obviously (up to a scalar factor of $\sqrt{2}$) an isometry $F : V_{-1} \rightarrow L^2([0,2])$ of Hilbert spaces.

The orthonormal basis $\{ \phi_I : |I| = 1/2 \}$ is mapped to the exponential basis. In particular we have

$$\hat{\phi} = m_{\phi} = mD_{2}\hat{\phi} .$$

We can read this equation as a constraint on $\phi$ to be a scaling function: $\hat{\phi}/D_{2}\hat{\phi}$, if suitably defined, should be a 2-periodic, locally $L^2$ function.

Observe that

$$\langle T_n\phi, \phi \rangle = \langle M_n\hat{\phi}, \hat{\phi} \rangle = \int e^{2\pi i \xi n} |\hat{\phi}(\xi)|^2 d\xi$$

$$= \sum_l \int_0^1 e^{2\pi i \eta l} |\hat{\phi}(\eta + l)|^2 d\eta$$

This gives

$$\sum_l |\hat{\phi}(\xi + l)|^2 d\xi = ||\phi||_2^2 = 1$$
This gives the following identity for the function $m_\phi$:

\[
1 = \sum_n \left| m_\phi(\xi + n)D_2^2\tilde{\phi}(\xi + n) \right|^2 \\
= \sum_{n \text{ even}} \left| m_\phi(\xi)D_2^2\tilde{\phi}(\xi + n) \right|^2 + \sum_{n \text{ odd}} \left| m_\phi(\xi)D_2^2\tilde{\phi}(\xi + n) \right|^2 \\
= \frac{1}{2} \left( |m_\phi(\xi)|^2 + |m_\phi(\xi + 1)|^2 \right) 
\]

(38)

Clearly the image $F(V_0)$ is the closed linear span of all functions $m_\phi(\xi)e^{2\pi i n}$. We know that these functions form (up to scalar) an orthonormal basis of $F(V_0)$. We could have derived (??) from this information without reference to the scaling function.

We can identify $L^2([0, 2])$ with the space $L^2([0, 1], \mathbb{R}^2)$ (all square integrable functions on $[0, 1]$ with values in the Hilbert space $\mathbb{R}^2$) via the map $G$ defined by

\[
Gm(\xi) = (m(\xi), m(\xi + 1))
\]

The space $GF(V_0)$ is then the space of all $\mu G(m_\phi)$ with $\mu \in L^2[0, 1]$, and the identification of $f \in V_0$ with $\mu f \in L^2([0, 1])$ is (up to scalar) an isometry.

Define $\psi \in V_{-1}$ by

\[
m_\psi(\xi) = e^{\pi i \xi}m_\phi(\xi + 1) .
\]

Then for all $\xi \in [0, 1]$ we easily see that $Gm_\psi(\xi)$ is orthogonal to $Gm_\phi(\xi)$. Thus the orthogonal complement of $GF(V_0)$ is easily seen to be the set of all functions $\mu G(m_\psi)$ with $\mu \in L^2([0, 1])$.

Since we have

\[
1 = \frac{1}{2} \left( |m_\phi(\xi)|^2 + |m_\psi(\xi + 1)|^2 \right)
\]

we see that the set of all $T_n\psi$ forms an orthonormal basis of its span. Moreover, this span is clearly equal to the complement $W_0$ of $V_0$ in $V_{-1}$.

Thus the set of $\psi_I$ with $I$ dyadic forms an orthonormal basis of $L^2(\mathbb{R})$

### 11.2 Regularity of wavelets

So far we have only discussed the $L^2$ theory of wavelets. In general one is certainly interested in having smoothness and decay of wavelets. However, just as in the Balian Low theorem for Gabor bases, it turns out that one cannot have Schwartz functions which are wavelets.

**Lemma 13** Let $\psi \in L^2(\mathbb{R})$ be a generating wavelet, i.e., the set $\psi_I$ is an orthonormal basis of $L^2(\mathbb{R})$. If $\phi$ has $n$ bounded continuous derivatives and

\[
|\phi(x)| \leq C(1 + |x|^{-n-1}) ,
\]

then $\tilde{\phi}(0)$ has a zero of order at least $n$. 
Observe that the conclusion of the lemma can be read that \( \phi \) has vanishing moments, i.e., its integral against all polynomials of degree at most \( n - 1 \) vanishes. The idea of the proof is that we will pair \( \phi \) with \( \phi_I \) with \( |I| \) very small, the scalar product being 0. Then The decay of \( \phi_I \) allows to pretend \( \phi_I \) is supported only near \( I \). The differentiability assumption on \( \phi \) allows us to pretend it equals its Taylor polynomial of degree \( n \) near the small interval \( I \). Thus \( \phi_I \) integrated against this polynomial vanishes. By varying \( I \) we can vary the polynomial, in fact we can obtain a basis of the set of polynomials of degree \( n \) this way. This will prove the lemma.

**Proof**

The proof goes by induction by \( n \). The lemma is trivial for \( n = 0 \). Let \( n \geq 0 \) and assume the lemma has been proved for all \( n' \leq n \).

If \( n \) is large, we can easily see that we find a primitive \( D^{-1}\phi \) (abuse of notation) of \( \phi \) which satisfies

\[
\left| D^{-1}\phi(x) \right| \leq C(1 + |x|^{-n-1})
\]

Namely, we just consider the integral \( \int_{-\infty}^{x} \phi(t) \, dt \), which gives the correct decay for \( x \to -\infty \), and the integral \( -\int_{x}^{\infty} \phi(t) \, dt \), which gives the correct decay for \( x \to +\infty \), and we observe that these two functions coincide because by induction hypothesis \( \phi \) has mean 0. Inductively we see that there is a \( n \)-th primitive of \( \phi \) which satisfies

\[
\left| D^{-n}\phi \right| \leq C(1 + |x|^{-2}).
\]

An easy argument using the full induction hypothesis shows that \( \mathcal{F}(D^{-1}\phi) \) vanishes of order \( n - 1 \).

We do \( n \) partial integrations to obtain

\[
0 = \langle \phi_I, \phi \rangle = \langle D^{-n}\phi_I, D^n\phi \rangle
\]

The right hand side is given by an absolutely integrable integral.

Now let \( J \) be any interval and \( I \) be a dyadic intervals such that \( AI \subset J \) for some large \( A \). Let \( M \) be the mean of \( D^n\phi \) on \( J \),and let \( M' \) be the mean of \( D^{-n}\phi \). If we assume that \( M \neq 0 \), then

\[
|M'| = |I|^{-\frac{1}{2}} \left| \int_J D^{-n}\phi_I(x) \, dx \right|
\]

\[
\leq |I|^{-\frac{1}{2}} \left| \int_J D^{-n}\phi_I(x) \, dx \right| + |I|^{-\frac{1}{2}} \| D^{-n}\phi_I \|_{L^1(J)}
\]

\[
\leq M^{-1}|I|^{-\frac{1}{2}} \left| \int_J D^{-n}\phi_I(x)D^n\phi(x) \, dx \right| + |I|^{-\frac{1}{2}} \| D^{-n}\phi_I \|_{L^1(J)} |J| \| D^n\phi \|_{\infty} + CA^{-1}
\]

\[
\leq M^{-1}|I|^{-\frac{1}{2}} \left| \int J D^{-n}\phi_I(x)D^n\phi(x) \, dx \right| + M^{-1}|I|^{-\frac{1}{2}} \| D^{-n}\phi_I \|_{L^1(J)} \| D^n\phi \|_{\infty} + C|J| + CA^{-1}
\]

\[
\leq CA^{-1} + C|J| + CA^{-1}
\]

Choosing \( A \) large enough gives \( M' \leq CJ \). If \( M' \) was not zero, this would imply that the averages of \( \phi \) over all sufficiently small intervals where 0, which would imply that
\( \phi \) was 0. This is a contradiction. Hence \( M' = 0 \) and \( D^{-n} \phi \) has mean 0. This proves that \( \hat{\phi} \) vanishes of order \( n + 1 \).

Assume we have a scaling function which does not have mean 0 (which is natural to assume). Then the conclusion of the above lemma says that

\[
\hat{\psi} = m_{\psi} D_2^2 \hat{\phi}
\]

vanishes of order \( n \) at 0. Hence \( m_{\psi} \) vanishes of order \( n \) at 0. This implies that \( m_{\phi} \) vanishes of order \( n \) at 1.

### 11.3 Construction of the scaling function

We would like to see examples of scaling functions. The characteristic function of \([0, 1]\) is a scaling function. It is interesting to observe by an easy calculation (exercise) that the above framework gives the Haar function as corresponding wavelet \( \psi \).

Next, we try for \( V_0 \) being the set of all continuous, piecewise linear functions with discontinuities in the derivative at most at the integer points. Clearly the scaled copies of \( V_0 \) are nested as required, and qualify for a multiresolution analysis.

The point is to find an orthogonal basis of translates in \( V_0 \). We can make the ansatz

\[
f(n) = \begin{cases} (-1)^n \gamma^n & \text{if } n \leq 0 \\ a \gamma^n & \text{if } n > 0 \end{cases}
\]

The parameters \( \gamma \) and \( a \) can be chosen so that \( f \) is orthogonal to \( T_l f \) and \( T_2 f \). Then it follows easily (exercise) that \( f \) is orthogonal to all \( T_l f \) with \( l > 0 \), which is what we needed. The corresponding set of wavelets is called the Franklin system, it consists again of linear splines.

One can do such constructions for splines of any order. These spline constructions however do not give compactly supported wavelets.

It turns out that one obtains compactly supported wavelets if one starts with a compactly supported scaling function. Then only finitely many terms in

\[
\phi = \sum_{|I|=1/2} \epsilon_I \phi_I
\]

are nonzero, because \( \langle \phi, \phi_I \rangle = 0 \) for all \( I \) sufficiently far away from the origin. Thus \( m_{\phi} \) is a trigonometric polynomial. By definition, \( m_{\psi} \) is also a trigonometric polynomial. Thus \( \psi \) is also a finite linear combination of \( \phi_I \) with \( |I| = 1/2 \), and hence it is also compactly supported.

Before we reconstruct \( \psi \), we will try to find candidates for the function \( m_{\phi} \). In fact we start with \( M = 2|m_{\phi}|^2 \). Then \( M \) is also a trigonometric polynomial of period 2, is positive, satisfies

\[
M(\xi) + M(\xi + 1) = 1
\]
and, since we would like differentiability of the wavelet, vanishes of order \(2n\) at 1. We make the ansatz

\[
M(\xi) = P(1 - \cos^2(\pi \xi/2)) \cos^2(\pi \xi/2),
\]

where \(P\) is some polynomial. This guarantees the vanishing of the right order at 1.

Setting \(\cos^2(\xi/2) = y\) then \((??)\) will be satisfied if we have for \(P\) the identity

\[
y^n P(1 - y) + (1 - y)^n P(y) = 1.
\]

The polynomials \(y^n\) and \((1 - y)^n\) have no common divisors, hence abstract algebra (Euclid’s algorithm) tells us that the equation

\[
y^n g_1(1 - y) + (1 - y)^n g_2(y) = 1
\]

has exactly one solution \(g_1, g_2\) with two polynomials \(g_1\) and \(g_2\) of order at most \(n - 1\). By symmetry and uniqueness we observe \(g_1(y) = g_2(1 - y)\). Hence \((??)\) has exactly one solution \(P\) of degree at most \(n - 1\) (there are more solutions of higher degree of course). We try to calculate the Taylor series of \(P\) around \(y = 0\). We observe for \(y\) close to 0:

\[
P(y) = (1 - y)^{-n} [1 - y^n P(1 - y)]
\]

This gives

\[
P(y) = (1 - y)^{-n} + O(y^n)
\]

By taking derivatives we can easily calculate the first \(n - 1\) coefficients of \(P\) and since we know \(P\) has order at most \(n - 1\) we obtain

\[
P(y) = \sum_{k=0}^{n-1} \binom{n - 1 + k}{k} y^k.
\]

Observe that \(P\) is nonnegative for \(y \geq 0\), hence \(M\) is nonnegative. Thus we can find a function \(m\) such that \(|m|^2 = M\). The point however is to choose \(m\) so that it is again a trigonometric polynomial.

Obviously we can write

\[
M(\xi) = \sum_{k=0}^{n-1} a_k \cos^k(\pi \xi)
\]

with real numbers \(a_k\). We can find and \(\alpha\) and roots \(c_j\) such that

\[
M(\xi) = \alpha \prod_{j=1}^{n-1} (\cos(\pi \xi) - c_j).
\]

Set \(z = e^{i\pi \xi}\). Then we have

\[
M(\xi) = \alpha \prod_{j=1}^{n-1} \left( \frac{z + \bar{z}}{2} - c_j \right)
\]

47
Since $|z| = 1$ we have $\overline{z} = z^{-1}$ and we can write

$$|M(\xi)| = \left|z^n \alpha \prod_{j=1}^{n-1} \left(\frac{z + \overline{z}}{2} - c_j\right)\right|$$

$$= \left|2^{-n} \alpha \prod_{j=1}^{n} \left(1 - 2c_j z + z^2\right)\right|$$

On the right hand side we have a polynomial in $z$. We plan to split this polynomial into linear factors. The factor

$$1 - 2c_j z + z^2$$

has two roots whose product is 1, hence they are of the form $r_j$ and $r_j^{-1}$. If $r_j$ is complex, then since $r_j + r_j^{-1}$ is real we have that $|r_j| = 1$. Thus $r_j = \frac{r_j}{\overline{r_j}}$ corresponds to a zero of $M$ and therefore must be a double (or higher, but even) zero because $M$ is positive. If $c_j$ is not real, then the complex conjugate $\overline{r_j}$ also appears and we have a quadruple of roots $r_j, r_j^{-1}, \overline{r_j}$ and $\overline{r_j}^{-1}$.

Thus we see that we can pair a root $r_j$ always with $\overline{r_j}^{-1}$, and therefore we can write

$$|M(\xi)| = \left|2^{-n} \alpha \prod_{j=0}^{n-1} (z - r_j)(z - \overline{r_j}^{-1})\right| .$$

For $|z| = 1$ we have

$$|z - \overline{r_j}^{-1}| = |z^{-1} - r_j^{-1}| = |r_j|^{-2} |z - r_j| .$$

Therefore

$$|M(\xi)| = |\alpha'| \prod_{j=0}^{n-1} |z - r_j|^2 .$$

Defining

$$m(\xi) = \sqrt{|\alpha'|/2} \prod_{j=0}^{n-1} \left(e^{i\pi \xi} - r_j\right)$$

We see that $m$ is a trigonometric polynomial with $|m|^2 = M$.

From the above discussion we also see that each $r_j$ is either real or can be paired with its complex conjugate. Therefore we can assume that

$$m(\xi) = \sum_{k=0}^{n-1} c_k e^{i \pi k \xi}$$

with real coefficients $c_k$.

Now that we have a candidate for $m = m_\phi$, we try to find $\phi$. To avoid factors of $\sqrt{2}$ we define $\tilde{m} = \sqrt{2}m$.

The identity we need for $\phi$ is

$$\phi(\xi) = \tilde{m}(\xi)\phi(2^{-1}\xi)$$

48
Assuming that $\hat{\phi}(0) = 1$ and $\hat{\phi}$ is continuous at 0 we obtain by formal iteration

$$\phi(\xi) = \prod_{j=0}^{\infty} \tilde{m}(2^{-j}\xi) .$$

We shall study the existence of the limit on the right hand side.

We know that $\tilde{m}$ is a trigonometric polynomial, hence it is an entire function, and it satisfies satisfies $\tilde{m}(0) = 1$. Thus we have the estimate

$$|m(z) - 1| \leq C|z|$$

for $|z| \leq 1$ and, using (42) again,

$$m(z) \leq C e^{C|\text{Im}(z)|}$$

for all $z$.

First we study (42) on the ball $|z| \leq 1$. Since

$$\sum_{j=0}^{\infty} |M(z) - 1| \leq \sum_{j=0}^{\infty} C 2^{-j} \leq 2C$$

is finite uniformly in $|z| \leq 1$, by elementary calculus the product (42) converges uniformly for $|z| \leq 1$. Since all factors are holomorphic, it converges to a holomorphic function.

Let $B_k$ the ball around the origin of radius $2^k$. We have

$$\prod_{j=0}^{\infty} \tilde{m}(2^{-j}\xi) = \prod_{j=0}^{k} \tilde{m}(2^{-j}\xi) \prod_{j=k}^{\infty} \tilde{m}(2^{-j}2^{-k-1}\xi) .$$

We see from the previous result that the second factor on the right hand side converges, hence the whole product converges. To estimate this function, we only have to estimate the first factor on the right hand side (the second one being bounded by a constant)

$$\left| \prod_{j=0}^{k} \tilde{m}(2^{-j}z) \right| \leq \prod_{j=0}^{k} C e^{C^2 |j| \text{Im}(z)}}$$

$$\leq C^k e^{C^2 |\text{Im}(z)|}$$

For all $z$ in the annulus $B_k \setminus B_{k-1}$ we therefore have

$$\left| \prod_{j=0}^{\infty} \tilde{m}(2^{-j}) \right| \leq C |z|^C e^{C|\text{Im}(z)|}$$

By the Paley Wiener theorem we find a compactly supported distribution $\phi$ such that

$$\hat{\phi}(\xi) = \prod_{j=0}^{\infty} \tilde{m}(2^{-j}\xi) .$$
We would like to see that \( \phi \) or equivalently \( \hat{\phi} \) is in \( L^2 \). To this end define on \( \mathbb{R} \) for \( k > 0 \)

\[
f_k = \prod_{j=0}^{k} \tilde{m}(2^{-j} \xi)1_{[-2^k, 2^k]}(\xi)
\]

Then we have, using that \( \tilde{m} \) has period 2,

\[
\|f_k\|_2^2 = \int_{-2^k}^{2^k} \prod_{j=0}^{k} |\tilde{m}(2^{-j} \xi)|^2 \, d\xi
\]

\[
\|f_k\|_2^2 = \int_{0}^{2^{k+1}} \prod_{j=0}^{k} |\tilde{m}(2^{-j} \xi)|^2 \, d\xi
\]

\[
\|f_k\|_2^2 = \int_{0}^{2^k} \prod_{j=0}^{k-1} |\tilde{m}(2^{-j} \xi)|^2 \left[ |\tilde{m}(2^{-k} \xi)|^2 + |\tilde{m}(2^{-k} \xi + 1)|^2 \right] \, d\xi
\]

\[
\|f_k\|_2^2 = \int_{0}^{2^k} \prod_{j=0}^{k-1} |\tilde{m}(2^{-j} \xi)|^2 \, d\xi \\
= \|f_{k-1}\|_2^2
\]

By induction

\[
\|f_k\|_2^2 = \|f_0\|_2^2 = \int_{-1}^{1} |\tilde{m}(\xi)|^2 \, d\xi = \int_{0}^{1} 1 \, d\xi = 1
\]

Since \( f_k \) converges pointwise to \( \hat{\phi} \), we have that \( \hat{\phi} \) is in \( L^2 \) by Fatou’s lemma.

Thus we have our compactly supported \( \phi \in L^2 \) as a candidate for the scaling function.

Given \( \phi \) we define \( \psi \) as before. We claim that for each \( f \in L^2 \) we have

\[
\|f\|_2^2 = \sum_I |\langle f, \psi_I \rangle|^2
\]

To this end we first observe that

\[
\sum_{|I|=1/2} |\langle f, \phi_I \rangle|^2 = \sum_{|I|=1} |\langle f, \phi_I \rangle|^2 + \sum_{|I|=1} |\langle f, \psi_I \rangle|^2
\]

Namely, the left hand side is equal to

\[
\sum_{|I|=1/2} |\langle \tilde{f}, \phi_I \rangle|^2
\]

\[
= \sum_{n} 2^{-1} \left| \int \tilde{f}(\xi) \phi(\xi/2)e^{\pi in\xi} \, d\xi \right|^2
\]

By Plancherel, this is equal to

\[
= \sum_{n} 2^{-\frac{1}{2}} \int_{0}^{2} \left| \sum_{k} \tilde{f}(\xi + 2k) \phi(\xi/2 + k) \right|^2 \, d\xi
\]

50
\[
= \sum_n \int_0^1 \left| \sum_k \hat{f}(\xi + 2k) \tilde{\phi}(\xi + 2k)/2 \right|^2 + \left| \sum_k \hat{f}(\xi + 2k + 1) \tilde{\phi}((\xi + 2k + 1)/2) \right|^2 \, d\xi \\
= \sum_n \int_0^1 \left| \sum_k \hat{f}(\xi + 2k) \tilde{\phi}(\xi + 2k)/2 m_\phi(\xi + 2k)/2 + \right. \\
\sum_k \hat{f}(\xi + 2k + 1) \tilde{\phi}((\xi + 2k + 1)/2) m_\phi(\xi + 2k + 1) \right|^2 \, d\xi \\
= \sum_n \int_0^1 \left| \sum_k \hat{f}(\xi + 2k) \tilde{\phi}(\xi + 2k)/2 m_\psi(\xi + 2k)/2 + \right. \\
\sum_k \hat{f}(\xi + 2k + 1) \tilde{\phi}((\xi + 2k + 1)/2) m_\psi(\xi + 2k + 1) \right|^2 \, d\xi \\
= \sum_n \int_0^1 \left| \sum_k \hat{f}(\xi + k) \tilde{\phi}(\xi + k) \right|^2 \, d\xi + \int_0^1 \left| \sum_k \hat{f}(\xi + k) \tilde{\psi}(\xi + k) \right|^2 \, d\xi
\]
