COMPUTING HOMOLOGICAL RESIDUE FIELDS
IN ALGEBRA AND TOPOLOGY

PAUL BALMER AND JAMES C. CAMERON

Abstract. We determine the homological residue fields, in the sense of tensor-triangular geometry, in a series of concrete examples ranging from topological stable homotopy theory to modular representation theory of finite groups.

1. Introduction

One important question in tensor-triangular geometry is the existence of residue fields. Just as we can reduce some problems in commutative algebra to problems in linear algebra by passing to residue fields, we would like to study general tensor-triangulated categories via 'field like' ones. Indeed, in key examples of tensor-triangulated categories such fields do exist: In the stable homotopy category we have the Morava K-theories, in the stable module category of a finite group scheme over a field we can consider \( \pi \)-points, and of course for the derived category of a commutative ring we have ordinary residue fields.

Even though residue fields exist in those examples, at the moment there is no tensor-triangular construction of them and it is not known if they always exist, beyond very special cases [Mat17]. It is not even known exactly what properties one should expect from a residue field functor \( F: T \to \mathcal{F} \) from our tensor-triangulated category of interest \( T \) to such a tensor-triangulated field \( \mathcal{F} \). In particular, some of the examples above fail to give symmetric tensor functors or tensor functors at all.

The recent work [BKS19, Bal20b, Bal20a] introduced and explored homological residue fields as an alternative that exists in broad generality and is always tensor-friendly. They consist of symmetric monoidal homological functors

\[
\bar{h}_B : T \to \bar{A}_B
\]

from \( T \) to 'simple' abelian categories \( \bar{A}_B \). One such functor exists for each so-called homological prime \( B \), as recalled in Section 2. These homological residue fields collectively detect the nilpotence of maps [Bal20b] and they give rise to a support theory for not necessarily compact objects [Bal20a].

Homological residue fields are undeniably useful but they are defined in a rather abstract manner and it is not clear how they relate to the tensor-triangulated residue fields \( F: T \to \mathcal{F} \) that partially exist in examples. For each homological prime \( B \), there is a canonical pure-injective object \( E_B \) of \( T \) that completely determines the homological residue field (1.1). Given a functor \( F: T \to \mathcal{F} \) to a tensor-triangulated field satisfying mild assumptions, there is a corresponding homological prime \( B \).

In the standard examples of such $F: \mathcal{T} \to \mathcal{F}$, it is desirable to determine the corresponding pure-injective $E_{\mathcal{B}}$ and residue category $\mathcal{A}_{\mathcal{B}}$. Our first contribution is to show that $E_{\mathcal{B}}$ is a direct summand of $U(1)$, where $U$ is right adjoint to $F$. (The existence of $U$ is a mild assumption, by Brown Representability.)

**Theorem (Theorem 3.1).** Let $F: \mathcal{T} \to \mathcal{F}$ be a monoidal exact functor to a tensor triangulated field and suppose that $F$ admits a right adjoint $U$. Then the pure-injective object $E_{\mathcal{B}} \in \mathcal{T}$ is a direct summand of $U(1)$.

In the examples of the topological stable homotopy category and of the derived category of a commutative ring, this $U(1)$ is respectively a Morava $K$-theory spectrum and a residue field. These are indecomposable objects. So we conclude that for these examples the potentially mysterious $E_{\mathcal{B}}$ coincides with the better understood ring object $U(1)$. See Corollary 3.5 and Corollary 3.3. The latter vastly generalizes the case of a discrete valuation ring obtained in [BKS19, Example 6.23].

In the case of the stable module category of a finite group scheme, there is a complication because the best candidates for tensor-triangulated fields – associated to $\pi$-points – are almost never monoidal functors for the tensor product coming from the group Hopf algebra structure. However, in the case of the stable module category of an elementary abelian $p$-group with the $p$-restricted Lie algebra tensor product structure, $\pi$-points do give tensor functors and we show in Corollary 3.11 that in this case the pure-injective $E_{\mathcal{B}}$ is again determined by the $\pi$-point.

In addition to understanding the pure-injective object $E_{\mathcal{B}}$ we would like to describe the abelian category $\mathcal{A}_{\mathcal{B}}$ in which a homological residue field takes its values. When $\mathcal{B}$ arises from a tensor-triangular field $F: \mathcal{T} \to \mathcal{F}$ we would like to relate $\mathcal{A}_{\mathcal{B}}$ and $\mathcal{F}$. Our second contribution is to do just this. The adjunction $F \dashv U$ gives a comonad $FU$ on $\mathcal{F}$. This comonad $FU$ then gives a comonad $\hat{FU}$ on the abelian category of (functor) $\mathcal{F}^c$-modules, where $\mathcal{F}^c$ denotes the compact objects of $\mathcal{F}$; see details in Section 2. The Eilenberg-Moore category of comodules (a. k. a. coalgebras) for this comonad $\hat{FU}$ is precisely the homological residue field $\mathcal{A}_{\mathcal{B}}$.

**Theorem (Theorem 4.2).** Let $F: \mathcal{T} \to \mathcal{F}$ be a monoidal functor with right adjoint $U$, where $\mathcal{F}$ is a tensor triangulated field. The category of comodules for the comonad $\hat{FU}$ on the functor category of $\mathcal{F}^c$-modules is equivalent to the homological residue field $\mathcal{A}_{\mathcal{B}}$ corresponding to $F$.

In cases where the tensor-triangulated field $\mathcal{F}$ in question is semisimple, such as the examples in topology and commutative algebra, this abelian category of $\mathcal{F}^c$-modules is just $\mathcal{F}$ itself. So the homological residue field $\mathcal{A}_{\mathcal{B}}$ is the category of comodules for an explicit comonad on $\mathcal{F}$ itself. Let us rephrase this result in heuristic terms. When the residue field functor $F: \mathcal{T} \to \mathcal{F}$ takes values in a semi-simple triangulated category $\mathcal{F}$ (i.e. one that is also abelian), then the abstractly constructed $\mathcal{A}_{\mathcal{B}}$ contains more information than $\mathcal{F}$. There is a faithful exact functor $\mathcal{A}_{\mathcal{B}} \to \mathcal{F}$ but objects of $\mathcal{A}_{\mathcal{B}}$ ‘remember’ more information than just being an object of $\mathcal{F}$, they remember that they come from $\mathcal{T}$ via $F$. This additional information is encoded in the comodule structure with respect to $FU: \mathcal{T} \to \mathcal{T}$.

Section 2 sets up the stage. We prove our two theorems in Sections 3 and 4.

**Acknowledgements.** We would like to thank Jacob Lurie for an interesting discussion about this topic, that made us realize that the monadic adjunction of [BKS19, §6] also had the comonadicity property of Section 4.
2. Background on homological residue fields

In this section we recall some definitions and properties of the category of modules of a tensor triangulated category and of homological residue fields. By a big tt-category $\mathcal{T}$, we mean a compact-rigidly generated tensor-triangulated category, as in [BKS19]. The (small) tt-subcategory of compact and rigid objects is denoted $\mathcal{T}^c$.

2.1. Recollection. For $\mathcal{T}$ a big tt-category, the (functor) category of $\mathcal{T}^c$-modules $\mathcal{A} = \text{Mod-}\mathcal{T}^c$ is the category of additive functors from $(\mathcal{T}^c)^{\text{op}}$ to abelian groups. This is a Grothendieck category, hence admits enough injectives. The subcategory of finitely presented objects of $\mathcal{A}$ is denoted $\mathcal{A}^{fp} = \text{mod-}\mathcal{T}^c$. We have a restricted Yoneda functor $h: \mathcal{T} \to \mathcal{A}$ defined by $h(X)(-) = \hat{X}(-) := \text{Hom}_\mathcal{T}(-, X)\vert_{\mathcal{T}^c}$ for every $X \in \mathcal{T}$. This gives a commutative diagram

$$
\begin{array}{ccc}
\mathcal{T}^c & \xrightarrow{\hat{\cdot}} & \mathcal{A}^{fp} \\
\downarrow & & \downarrow \\
\mathcal{T} & \xrightarrow{h} & \mathcal{A}
\end{array}
$$

whose first row is the usual Yoneda embedding for $\mathcal{T}^c$.

For $\mathcal{B}$ a homological prime, i.e. a maximal Serre tensor-ideal of $\mathcal{A}^{fp}$, we obtain the homological residue field $\bar{\mathcal{A}}_{\mathcal{B}} := \mathcal{A}/\text{Loc}(\mathcal{B})$. In that quotient $\bar{\mathcal{A}}_{\mathcal{B}}$ we write $\bar{X}$ instead of $Q(\hat{X})$, for $X \in \mathcal{T}$. In $\bar{\mathcal{A}}_{\mathcal{B}}$ we can take the injective hull of the unit and by [BKS19, §3] this is of the form $\bar{E}_{\mathcal{B}}$ for a canonical pure-injective $E_{\mathcal{B}}$ of $\mathcal{T}^c$. Furthermore we have $\text{Loc}(\mathcal{B}) = \text{Ker}(\hat{E}_{\mathcal{B}} \otimes -)$ in $\mathcal{A}$.

A tt-field is a big tt-category $\mathcal{F}$ such that every object of $\mathcal{F}$ is a coproduct of compact objects and such that tensoring with any object is faithful. Equivalently by [BKS19, Theorem 5.21], a big tt-category $\mathcal{F}$ is a tt-field if and only if for every non-zero $X \in \mathcal{F}$ the internal hom functor $\text{hom}_\mathcal{F}(-, X): \mathcal{F}^{\text{op}} \to \mathcal{F}$ is faithful.

We now summarize and mildly generalize some results from [BKS19, Bal20a].

2.2. Lemma. Given a big tensor-triangulated category $\mathcal{T}$, a tensor-triangulated field $\mathcal{F}$, and a monoidal exact functor $F: \mathcal{T} \to \mathcal{F}$ with right adjoint $U$, we have the following diagram:

$$
\begin{array}{ccc}
\mathcal{T} & \xrightarrow{\hat{\cdot}} & \text{Mod-}\mathcal{T}^c = \mathcal{A} \\
\downarrow & & \downarrow \\
\mathcal{F} & \xrightarrow{U} & \text{Mod-}\mathcal{F}^c
\end{array}
$$

$$(2.3)$$

in which $\hat{F}$ is the exact cocontinuous functor induced by $F$, the functor $Q$ is the Gabriel quotient with respect to $\text{Ker}(\hat{F})$ and the functor $\bar{F}$ is induced by the universal property, hence $\bar{F} = \hat{F} Q$ and $\bar{F}$ is exact and faithful. We have adjunctions $F \dashv U$, $\bar{F} \dashv \bar{U}$, and $Q \dashv R$, as depicted. Also, $\hat{F} \circ h = h F$ and $\bar{U} \circ h = h U$.

We have that $\mathcal{B} := \text{Ker}(\bar{F}) \cap \mathcal{A}^{fp}$ is a homological prime and $\text{Ker}(\bar{F}) = \text{Loc}(\mathcal{B})$. Therefore $\bar{h}_{\mathcal{B}} = Q \circ h: \mathcal{T} \to \bar{\mathcal{A}}_{\mathcal{B}}$ is a homological residue field of $\mathcal{T}$. 
Proof. This is a more general version of [BKS19, Diagram 6.19], whose proof works without assuming $F$ symmetric monoidal. We do not need Condition (3) in [BKS19, Hypothesis 6.1] either, as this was later used only to guarantee faithfulness of $\bar{U}$, which we do not use here. \hfill \Box

2.4. Remark. It is important that $F$ is only assumed to be monoidal but not symmetric monoidal. In other words $F(X \otimes Y)$ is naturally isomorphic to $F(X) \otimes F(Y)$, but this isomorphism is not necessarily compatible with the braiding. In one of the key examples coming from Morava $K$-theory the functor $F$ cannot be made symmetric monoidal but it is monoidal. The reason we ask that $F$ is monoidal is so that the kernel of $\bar{F}$ is a tensor-ideal. The monoidality of $F$ is a reasonable condition that guarantees this but because $F$ is not monoidal in some examples (e.g. in modular representation theory) there may be better hypotheses to be discovered.

3. The pure-injective $E_B$ in examples

We now would like to study the pure-injective object $E_B$ that determines the homological residue field corresponding to $F: \mathcal{T} \to \mathcal{T}$ as in Section 2.

3.1. Theorem. With the hypotheses as in Lemma 2.2, the object $U(\bar{1})$ is pure-injective in $\mathcal{T}$ and admits $E_B$ as a direct summand.

Proof. The functor $\bar{F}$ is exact, so $\bar{U}$ preserves injectives. Similarly, $U$ preserves pure-injectives. Since $\mathcal{T}$ is pure semisimple, $\bar{1}$ is pure-injective in $\mathcal{T}$. Therefore $U(\bar{1})$ is pure-injective and $\bar{U}(\bar{1}) = \bar{U}(\bar{1})$ is injective in $\mathcal{A}_B$. Moreover, by the $F \dashv \bar{U}$ adjunction we have that $\bar{F}(1) \to \bar{F}F(1)$ is a monomorphism. As $\bar{F}$ is faithful, we deduce that $1 \to \bar{U}F(1) = \bar{U}(1)$ is a monomorphism in $\mathcal{A}_B$. But $1 \to E_B$ is the injective hull in $\mathcal{A}_B$. Hence $\bar{U}(1) = E_B \oplus \bar{X}$ for some other pure-injective $X \in \mathcal{T}$.

Recall by [BKS19, Corollary 2.18 (c)] that for any injective $I$ in $\mathcal{A}_B$ and any $X \in \mathcal{T}$ we have that $\text{Hom}_\mathcal{T}(X, I) \cong \text{Hom}_{\mathcal{A}_B}(\bar{X}, I)$. So, since $\bar{U}(1)$ has $E_B$ as a summand in $\mathcal{A}_B$, it follows that $U(1)$ also has $E_B$ as a summand in $\mathcal{T}$. \hfill \Box

Now, in several examples $U(\bar{1})$ is a familiar object and it does not have any non-trivial summands.

3.2. Lemma. Suppose that $\mathcal{T}$ is a tensor-triangulated category that is generated by its $\otimes$-unit $1$. For $E \in \mathcal{T}$ if $\pi_* E := \text{Hom}(\Sigma^* \bar{1}, E)$ is indecomposable as a $\pi_* \bar{1}$-module then $E$ is indecomposable in $\mathcal{T}$.

Proof. We have $\pi_*(E' \oplus E'') \cong \pi_* E' \oplus \pi_* E''$ as $\pi_* \bar{1}$-modules. So the result follows immediately from $\pi_*$ being a conservative functor when $\mathcal{T}$ is generated by $\bar{1}$. \hfill \Box

3.3. Corollary. Let $R$ be a noetherian ring with derived category $\mathcal{T} = \text{D}(R)$ and let $B$ be a homological prime corresponding to the prime $p$ of $\text{Spec}(R) \cong \text{Spec}(\text{D}^{\text{perf}}(R))$. Then the pure-injective object $E_B$ is isomorphic to the residue field $\kappa(p)[0]$.

Proof. The homological prime $B$ is obtained as in the setting of Theorem 3.1 from the residue field functor $F: \text{D}(R) \to \text{D}(\kappa(p))$. By the above discussion, we just need to show that $U(\bar{1}) = \kappa(p)[0]$ does not split in $\text{D}(R)$. By Lemma 3.2 this follows from the fact that $\kappa(p)$ does not split as an $R$-module. \hfill \Box

Morava $K$-theories furnish all of the $\text{tt}$-primes in the stable homotopy category $\text{SH}$ by [HS98]. Indeed, each $\text{tt}$-prime is of the form $\ker(\text{SH}^c \to K(p, n)_\text{-Mod})$ given by $X \mapsto K(p, n)_\ast X$ where $p$ is a prime and $n$ a natural number or $\infty$. (We
write $K(p, \infty)$ for $\mathbb{H} \mathbb{Z}/p$.) Each spectrum $K(p, n)$ is a ring spectrum but they are in general not $E_{\infty}$: the $K(2, n)$ are in general not even commutative rings in the homotopy category [Würl86]. Nevertheless the homotopy category of $K(p, n)$-modules is equivalent via taking homotopy groups to the category $K(p, n)_* \text{-GrMod}$ of graded $K(p, n)_*$-modules, which is a semi-simple tensor triangulated category. The $K(p, n)$-homology has a Künneth isomorphism which shows that the functor $\text{SH} \rightarrow K(p, n)_* \text{-Mod}$ is monoidal, although not necessarily symmetric monoidal.

Because $K(p, n)_*$ is a graded field, the category $K(p, n)_* \text{-GrMod}$ is a tensor triangulated field. So for each Morava $K$-theory we have a homological residue field $A_B$ and a pure-injective $E_B$ that we want to identify.

3.4. Lemma. Each Morava $K$-theory spectrum $K(p, n)$ is indecomposable in the stable homotopy category.

Proof. This follows from [HS98, Proposition 1.10], which states that any retract in $\text{SH}$ of a $K(p, n)$-module is a wedge of shifts of $K(p, n)$. Because $K(p, n)_*$ is either $\mathbb{F}_p$ or $\mathbb{0}$ in each dimension, it follows that $K(p, n)$ itself is indecomposable in $\text{SH}$. □

3.5. Corollary. For $B$ the homological prime of $\text{Spc}^b(\text{SH}^c)$ corresponding to $K(p, n)$, we have an isomorphism $E_B \simeq K(p, n)$ in $\text{SH}$.

Proof. Because $E_B$ is constructed as in Lemma 2.2 from the monoidal functor $F: \text{SH} \rightarrow K(p, n)_* \text{-Mod}$, by Theorem 3.1 we have that $E_B$ is a summand of $K(p, n)$. Therefore by Lemma 3.4 we have that $E_B$ is isomorphic to $K(p, n)$. □

3.6. Remark. The tt-primes of the $G$-equivariant stable homotopy category $\text{SH}(G)$ have been determined for $G$ finite in [BS17] and for general compact Lie groups $G$ in [BGH20]. They are all pulled-back from the chromatic ones in $\text{SH}$ via geometric fixed-point functors $\Phi^H: \text{SH}(G) \rightarrow \text{SH}$ for (closed) subgroups $H \leq G$. The functor $\Phi^H$ admits a right adjoint that we denote $U^H: \text{SH} \rightarrow \text{SH}(G)$. It follows that the pure-injective $E_B$ corresponding to $H$ and $K(p, n)$ is a summand of $U^H(K(p, n))$. When $H = G$ it is easy to show that these objects remain indecomposable in $\text{SH}(G)$ but we do not know whether this holds in general.

3.7. Remark. We have shown that in two of the main examples, the derived category of a noetherian ring and the stable homotopy category, the $E_B$ are ring objects. It is natural to wonder if this is always the case. By [BKS19], there is always a map $E_B \otimes E_B \rightarrow E_B$ retracting $E_B \otimes \eta$ where $\eta: 1 \rightarrow E_B$ comes from the definition of $E_B$ as the injective hull of 1. Those ‘weak rings’ $E_B$ would be actual rings if they were always equal to $U(1)$ but this is not necessarily true. Indeed, one can ‘overshoot’ the mark as explained in the following example.

3.8. Example. For a field extension $K \rightarrow L$, we have a tt-functor on derived categories $\mathcal{T} := D(K) \rightarrow D(L) =: \mathcal{F}$. Note that $\mathcal{F}$ is already a tt-field itself. The pure-injective $E_B$ associated to the only homological prime $B = 0$ of $\mathcal{F}$ is the $\otimes$-unit $\mathbf{1}_{\mathcal{F}} = K[0]$ itself, whereas $U(\mathbf{1}_{\mathcal{F}})$ is $L[0]$ and of course $L \simeq K^{\dim_K(L)}$.

Our final example is that of $\pi$-points in modular representation theory. Let $k$ be a field of characteristic $p$ dividing the order of a finite group $G$. Recall [FP05] that a $\pi$-point of the group ring $kG$ is a flat algebra homomorphism $\pi: KC_p \rightarrow KG$ which factors through $KA$ for $A$ an elementary abelian $p$-subgroup of $G$ where $K$ is a field extension of $k$. There is a corresponding functor $\pi^*: \text{Stab} kG \rightarrow \text{Stab} KC_p$ composed of extension-of-scalars to $K$ followed by restriction along $\pi$. This functor
acts like a residue field functor, but frustratingly this functor is not monoidal, and so Lemma 2.2 cannot be used to construct a homological residue field.

However, every $\pi$-point is equivalent to one where the homomorphism $KC_p \cong K[t]/t^p \to K[x_1, \ldots, x_n]/(x_i^p) \cong KA$ is of the form $t \mapsto \sum_{i=1}^n \alpha_i x_i$ for $\alpha = (\alpha_1, \ldots, \alpha_n) \in K^n \setminus \{0\}$. We will denote such a map by $\pi_\alpha$. Up to equivalence, one indexes the $\pi$-points $\pi_{\alpha}$ by the closed points of $\mathbb{P}_K^\vee \simeq \text{Spec}(\text{Stab}(KA)^*)$. Allowing all field extensions $K/k$, the $\pi_{\alpha}$ parameterize all points of $\text{Spec}(\text{Stab}(kA)^*)$.

The map $\pi_\alpha$ is a Hopf algebra map when the source and target have the Hopf algebra structure coming from thinking of $KC_p$ and $KA$ as the restricted enveloping algebra of a $p$-restricted Lie algebra. Consequently the functor $\pi_\alpha^* : \text{Stab}(KA) \to \text{Stab}(KC_p)$ is a monoidal functor with respect to this different tensor. To put it in terms of formulas, we define $\Delta$ in $KA = K[x_1, \ldots, x_n]/(x_i^p)$ by $\Delta(x_i) = x_i \otimes 1 + 1 \otimes x_i$. See [CI17] for a discussion of these structures.

3.9. Convention. From now on we use the Hopf algebra structure on $KA$ coming from the $p$-restricted Lie algebra structure to put a tensor structure on $\text{Stab}(kA)$.

The $\pi_\alpha^* : \text{Stab}(kA) \to \text{Stab}(KC_p)$ are now tensor-triangular residue field functors. So, there are corresponding homological residue fields $\text{Stab}(kA) \to \hat{A}_B$ and corresponding pure-injectives $E_B$ in $\text{Stab}(kA)$. We would like to relate the $\pi$-point to the pure-injective object. First, we note what $\pi$-points do on cohomology.

3.10. Lemma. Let $\pi_\alpha : kC_p \to kA$ be a $k$-rational $\pi$-point. For $p$ odd, the induced map on cohomology $\pi_\alpha^* : H^*(A, k) \cong k[\eta_1, \ldots, \eta_n] \otimes \Lambda(\xi_1, \ldots, \xi_n) \to k[\zeta] \otimes \Lambda(\omega) \cong H^*(C_p, k)$ is given by $\pi_\alpha^*(\eta_i) = \alpha_i^p \zeta$ and $\pi_\alpha^*(\xi_i) = \alpha_i \omega$ for all $i = 1, \ldots, n$. For $p = 2$, there is no exterior power and $\pi_\alpha^*(\eta_i) = \alpha_i \zeta$ for all $i = 1, \ldots, n$.

Proof. For the polynomial classes this is [Car83, Propositions 2.20 and 2.22] and the result for the exterior classes follows from the proof of the first proposition. \qed

(a) The pure-injective $E_B$ of $\text{Stab}(kA)$ associated to a (closed) $k$-rational $\pi$-point $\pi_\alpha : kC_p \to kA$ is given by $\text{coind}_{kC_p}^{kA} k = \text{Hom}_{kC_p}(kA, k)$.

(b) Let $K/k$ be an extension. The pure-injective $E_B$ of $\text{Stab}(kA)$ associated to a $\pi$-point $\pi_\alpha : K\text{C}_p \to K\text{A}$ is a summand of $\text{res}_{kC_p}^{kA} \text{coind}_{kC_p}^{kA} K = \text{Hom}_{kC_p}(K\text{A}, K)$.

Proof. The second claim follows immediately from Theorem 3.1. The first claim will follow from the second (with $K = k$) if we can show that $\text{coind}_{kC_p}^{kA} k$ is indecomposable in $\text{Stab}(kA)$. From Lemma 3.2 it is enough to show that $\pi_\alpha(\text{coind}_{kC_p}^{kA} k)$ is indecomposable as a $\pi_\alpha k = \hat{H}^{*-}(A, k)$ module. But $\pi_\alpha(\text{coind}_{kC_p}^{kA} k) = \hat{H}^{*-}(C_p, k)$ with the module structure induced by the restriction map $\pi_\alpha^* : \hat{H}^*(A, k) \to \hat{H}^*(C_p, k)$ and this module is indecomposable by Lemma 3.10. \qed

3.12. Remark. In (b), there is no reason for the object $\text{res}_{kC_p}^{kA} \text{coind}_{kC_p}^{kA} K$ to be indecomposable, for one can ‘overshoot’ the right residue field as in Example 3.8.

3.13. Remark. Because $\mathcal{K} = \text{Stab}(kA)^*$ is generated by the unit, all thick subcategories are tensor-ideals, and hence the two different tensor structures on $\mathcal{K}$ give the same tensor-triangular spectrum. However, this does not imply that the homological spectra are in canonical bijection. In other words it is not necessarily the case that if $I$ is a Serre tensor-ideal of mod-$\mathcal{K}$ in the restricted Lie algebra tensor
structure then it is also a Serre tensor-ideal in the group tensor algebra structure. Therefore these results do not give classifications of the objects $E_B$ of $\text{Stab}(kA)$ with the group tensor structure, \textit{a priori}. Further research might tell.

4. HOMOLOGICAL RESIDUE FIELDS AS COMODULES

Recall Diagram (2.3). It is proved in [BKS19] that $\tilde{U}$ is monadic under the assumption that $U$ is faithful, \textit{i.e.} that $F$ is surjective-up-to-summands (an assumption we do not make here). In that case, one can describe $\text{Mod-}\mathcal{F}$ as the Eilenberg-Moore category of $\tilde{U}(1)$-modules in $\mathcal{A}_B$. This was the logic of [BKS19]: How to recover $F$ from the abstract $\mathcal{A}_B$?

However, in many of the examples, the category $\mathcal{F}$ is more familiar than $\mathcal{A}_B$, and we would rather like a description of $\mathcal{A}_B$ in terms of $\mathcal{F}$. Towards this end, we will show that $\tilde{F}$ is co-monadic, so $\mathcal{A}_B$ is the Eilenberg-Moore category of comodules for the comonad $\tilde{FU}$ over $\text{Mod-}\mathcal{F}$.

For this, we recall the dual version of the Beck monadicity theorem. Denote the Eilenberg-Moore category of comodules for a comonad $H$ on $\mathcal{D}$ by $H\text{-CoMod}_\mathcal{D}$.

4.1. Lemma. Suppose we have an adjunction $F: \mathcal{C} \rightleftarrows \mathcal{D}: U$ and that $\mathcal{C}$ and $\mathcal{D}$ have equalizers and $F$ is conservative and preserves equalizers. Then $F$ is comonadic, \textit{i.e.} the comparison functor $f: \mathcal{C} \to \tilde{FU}\text{-CoMod}_\mathcal{D}$ is an equivalence of categories.

\textbf{Proof.} This follows from the usual Beck Monadicity theorem [ML98] applied to the opposite category. \hfill $\square$

4.2. Theorem. In (2.3) the functor $\tilde{F}$ is comonadic, so $\mathcal{A}_B$ is equivalent to the Eilenberg-Moore category of comodules for the comonad $\tilde{FU}$.

\textbf{Proof.} The conditions of Lemma 4.1 hold since $\tilde{F}$ is conservative and exact and the categories involved are abelian and hence have all equalizers. \hfill $\square$

4.3. Remark. We have $\tilde{FU} \cong \tilde{F}U \cong \tilde{F}QR \tilde{U} \cong \tilde{F}U$. The functor $\tilde{F}$ is not conservative in general, so $\tilde{F}$ itself is not comonadic.

In two of the examples at hand, the stable homotopy category and the derived category of a ring, the tensor triangulated fields $\mathcal{F}$ in the picture are semisimple triangulated categories and hence are already abelian. So, the abelian category of (functor) modules on these tensor triangulated fields is just the tensor triangulated field $\mathcal{F}$ itself, \textit{i.e.} restricted Yoneda $h: \mathcal{F} \to \mathcal{F}\text{-Mod}$ is an equivalence.

4.4. Corollary. In the case of $\text{SH}$, the homological residue category $\tilde{A}_B$ for the homological prime $\mathcal{B}$ corresponding to a Morava $K$-theory spectrum $K(p,n)$ is equivalent to the Eilenberg-Moore category of comodules for the comonad $FU$ on the category of graded $K(p,n)$-modules, where $FU$ is associated to the free/forgetful adjunction $F: \text{SH} \rightleftarrows \text{Ho}(K(p,n)-\text{Mod}) \cong K(p,n)_*\text{-GrMod} : U$.

4.5. Corollary. In the case of $\text{D}(R)$ for $R$ a commutative noetherian ring, the homological residue category $\tilde{A}_B$ for the homological prime $\mathcal{B}$ corresponding to a Zariski point $i: \text{Spec}(\kappa(p)) \to \text{Spec} R$ is equivalent to the Eilenberg-Moore category of comodules for the comonad $L_i^* \circ i_*$ on graded $\kappa(p)$-modules, where $L_i^* \circ i_*$ is associated to the usual adjunction $L_i^*: \text{D}(R) \rightleftarrows \text{D}(\kappa(p)) \cong \kappa(p)_\text{-GrMod} : i_*$. 
Proof of Corollaries 4.4 and 4.5. By Theorem 4.2 we have that in these two cases the category $\mathcal{A}_B$ is equivalent to $FU$-comodules on $\mathcal{F}$, where $\mathcal{F}$ is respectively graded $K(p,n)_*$-modules and graded $\kappa(p)$-modules. Here we are using that the homotopy category of $K(p,n)$-modules and the derived category of $\kappa(p)$ are respectively graded $K(p,n)_*$-modules and graded $\kappa(p)$-modules. So, the claim follows from the fact that if $\mathcal{F}$ is a semisimple abelian category then $\mathcal{F}^c\text{-Mod} \cong \mathcal{F}$ and, under this equivalence, the comonad $\hat{FU}$ boils down to $FU$. □
