1. INTRODUCTION

In this course, assuming basic knowledge of complex analysis, we describe basics of elliptic modular forms. We plan to discuss the following four topics:

- (1) Spaces of modular forms and its rational structure,
- (2) Modular L-functions,
- (3) Rationality of L -values,
- (4) Congruences among cusp forms.

Date: January 5, 2019.

Basic references are [MFM, Chapters 1–4] and [LFE, Chapter 5]. We assume basic knowledge of algebraic number theory and complex analysis (including Riemann surfaces).

2. ELLIPTIC MODULAR FORMS

2.1. Congruence subgroups and the associated Riemann surface. Let $\Gamma_0(N) = \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathrm{SL}_2(\mathbb{Z}) \mid c \equiv 0 \pmod{N} \right\}$. This is a subgroup of finite index in $\mathrm{SL}_2(\mathbb{Z})$. A subgroup $\Gamma \subset \mathrm{SL}_2(\mathbb{Q})$ is said to be a congruence subgroup if there exists a positive integer N such that the following principal congruence subgroup of level N :

$$\Gamma(N) = \{ \alpha \in \mathrm{SL}_2(\mathbb{Z}) \mid \alpha \equiv 1 \pmod{N} \}$$

is a subgroup of finite index in Γ . More generally, we can generalize the notion of congruence subgroups to any number field K with integer ring O . A subgroup $\Gamma \subset \mathrm{SL}_2(K)$ is called a congruence subgroup if Γ contains as a subgroup of finite index

$$\Gamma(\mathfrak{N}) = \{ \alpha \in \mathrm{SL}_2(O) \mid \alpha \equiv 1 \pmod{\mathfrak{N}} \}$$

for a non-zero ideal \mathfrak{N} of O . A classical problem is

Problem 2.1. *Is every subgroup of finite index of $\mathrm{SL}_2(O)$ a congruence subgroup?*

This problem is called the *congruence subgroup problem*. In the case of SL_2 , this is solved affirmatively by Serre and others in 1970s if K is not \mathbb{Q} and not an imaginary quadratic field (see [CSP]). Ask yourself why this fails when $K = \mathbb{Q}$ (via complex analysis and homology theory).

Exercise 2.2. *Let $\mathbf{P}^1(A)$ be the projective space of dimension 1 over a ring A . Prove $[\mathrm{SL}_2(\mathbb{Z}) : \Gamma_0(N)] = |\mathbf{P}^1(\mathbb{Z}/N\mathbb{Z})| = N \prod_{\ell|N} (1 + \frac{1}{\ell})$ if N is square-free, where ℓ runs over all prime factors of N . Hint: Let $\begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathrm{SL}_2(\mathbb{Z})$ acts on $\mathbf{P}^1(A)$ by $z \mapsto \frac{az+b}{cz+d}$ and show that this is a transitive action if $A = \mathbb{Z}/N\mathbb{Z}$ and the stabilizer of ∞ is $\Gamma_0(N)$.*

We let $\begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathrm{GL}_2(\mathbb{C})$ acts on $\mathbf{P}^1(\mathbb{C}) = \mathbb{C} \cup \{\infty\}$ by $z \mapsto \frac{az+b}{cz+d}$ (by linear fractional transformation).

Exercise 2.3. *Prove the following facts:*

- (1) *there are two orbits of the action of $\mathrm{GL}_2(\mathbb{R})$ on $\mathbf{P}^1(\mathbb{C})$: $\mathbf{P}^1(\mathbb{R})$ and $\mathfrak{H} \sqcup \overline{\mathfrak{H}}$, where $\mathfrak{H} = \{z \in \mathbb{C} \mid \mathrm{Im}(z) > 0\}$ and $\overline{\mathfrak{H}} = \{z \in \mathbb{C} \mid \mathrm{Im}(z) < 0\}$.*
- (2) *the stabilizer of $i = \sqrt{-1}$ is the center times $\mathrm{SO}_2(\mathbb{R}) = \left\{ \begin{pmatrix} \cos(\theta) & \sin(\theta) \\ -\sin(\theta) & \cos(\theta) \end{pmatrix} \mid \theta \in \mathbb{R} \right\}$,*
- (3) *For $z \in \mathfrak{H}$ and $\Gamma_z = \{ \gamma \in \mathrm{SL}_2(\mathbb{Z}) \mid \gamma(z) = z \}$, Γ_z is an abelian group of order either 2, 4 or 6.*
- (4) *$\gamma \in \mathrm{GL}_2(\mathbb{R})$ with $\det(\gamma) < 0$ interchanges the upper half complex plane \mathfrak{H} and lower half complex plane $\overline{\mathfrak{H}}$,*
- (5) *the upper half complex plane is isomorphic to $\mathrm{SL}_2(\mathbb{R})/\mathrm{SO}_2(\mathbb{R})$ by $\mathrm{SL}_2(\mathbb{R}) \ni g \mapsto g(\sqrt{-1}) \in \mathfrak{H}$,*
- (6) *$\mathrm{SL}_2(\mathbb{R})$ is connected but $\mathrm{GL}_2(\mathbb{R})$ is not connected as topological space. How about $\mathrm{GL}_2(\mathbb{C})$?*

As a slightly more advanced fact, we note

Proposition 2.4. *Write $\text{Aut}(\mathfrak{H}^n)$ ($0 < n \in \mathbb{Z}$) for the holomorphic automorphisms of \mathfrak{H}^n . Then $\text{Aut}(\mathfrak{H}) = \text{PSL}_2(\mathbb{R})$. More generally writing \mathfrak{S}_n for the group of permutation of coordinates of \mathfrak{H}^n , we have $\text{Aut}(\mathfrak{H}^n) \cong \mathfrak{S}_n \times \text{PSL}_2(\mathbb{R})^n$.*

See any undergraduate text book of complex analysis to find a proof of $\text{Aut}(\mathfrak{H}) = \text{PSL}_2(\mathbb{R})$. The rest is an exercise.

Lemma 2.5. *The group $\text{SL}_2(\mathbb{Z})$ is generated by $\tau := \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$ and $\sigma := \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$.*

Proof. Let Γ be the subgroup generated by τ and σ inside $\text{SL}_2(\mathbb{Z})$. Suppose $\Gamma \neq \text{SL}_2(\mathbb{Z})$ and get a contradiction. Since $\sigma\tau^{-1}\sigma^{-1} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$ and $\sigma^2 = -1$, Γ contains any lower triangular elements in $\text{SL}_2(\mathbb{Z})$. Let

$$B = \min\{|b| : \begin{pmatrix} * & b \\ * & * \end{pmatrix} \in \text{SL}_2(\mathbb{Z}) - \Gamma\}.$$

Note that $B \neq 0$ as $\sigma\tau^{-1}\sigma^{-1} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \in \Gamma$. Take $\gamma = \begin{pmatrix} a & B \\ c & d \end{pmatrix} \in \text{SL}_2(\mathbb{Z}) - \Gamma$ and an integer m so that $|a - mB| < B$ (as a and B is co-prime by $\det(\gamma) = 1$). Then, by computation, we have $\gamma\sigma^{-1}\tau^m = \begin{pmatrix} -b & a-mB \\ -d & c-md \end{pmatrix} \in \Gamma$. This implies $\gamma \in \Gamma$, a contradiction. \square

Let Γ be a subgroup of $\text{SL}_2(\mathbb{R})$ and F be a connected sub-domain of \mathfrak{H} . The domain F is said to be a fundamental domain of Γ if the following three conditions are met:

- (1) $\mathfrak{H} = \bigcup_{\gamma \in \bar{\Gamma}} \gamma(F)$ for the image $\bar{\Gamma}$ of Γ in $\text{PSL}_2(\mathbb{R})$;
- (2) $F = \bar{U}$ for an open set U made up of all interior points of F ;
- (3) If $\gamma(U) \cap U = \emptyset$ for any $1 \neq \gamma \in \bar{\Gamma}$.

Corollary 2.6. *The set $F = \{z \in \mathfrak{H} : |z| \geq 1 \text{ and } |\text{Re}(z)| \leq \frac{1}{2}\}$ is a fundamental domain of $\text{SL}_2(\mathbb{Z})$ and $\int_F y^{-2} dx dy = \frac{\pi}{3}$.*

Proof. Here we give some heuristics (showing $\mathfrak{H} = \bigcup_{\gamma \in \text{SL}_2(\mathbb{Z})} \gamma(F)$). See [MFM, Theorem 4.1.2] for a detailed proof. Let $\Phi := \{z \in \mathfrak{H} : |\text{Re}(z)| \leq \frac{1}{2}\}$.

Pick $z \in \mathfrak{H}$. Since $\mathbb{Z}z + \mathbb{Z}$ is a lattice in \mathbb{C} , we can find $\alpha \in \text{SL}_2(\mathbb{Z})$ with minimal $|j(\alpha, z)|$ in $\{j(\gamma, z) := cz + d | \gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \text{SL}_2(\mathbb{Z})\}$. Let $z_0 = \alpha(z)$. Since $\text{Im}(\gamma(z)) = \text{Im}(z)/|j(\gamma, z)|^2$ and $|j(\gamma, z)|$ is minimal, we get $\text{Im}(z_0) \geq \text{Im}(\gamma(z_0))$ for all $\gamma \in \text{SL}_2(\mathbb{Z})$. This means

$$\text{Im}(z_0) \geq \text{Im}(\gamma\alpha(z)) = \text{Im}(\gamma(z_0))$$

for all $\gamma \in \text{SL}_2(\mathbb{Z})$. Take γ to be $\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$. Then we have

$$\text{Im}(z_0) \geq \text{Im}(-1/z_0) = \text{Im}(z_0)/|z_0|^2$$

which implies $|z_0|^2 \geq 1$.

By translation $z + m = \tau^m(z)$ (which does not change $\text{Im}(z)$), we can bring $z \in \mathfrak{H}$ inside Φ . Thus $\mathfrak{H} = \bigcup_{\gamma \in \text{SL}_2(\mathbb{Z})} \gamma(F)$.

We leave the verification of $\gamma(F^\circ) \cap F^\circ = \emptyset$ for $\pm 1 \neq \gamma \in \text{SL}_2(\mathbb{Z})$ as an exercise. \square

Exercise 2.7. *Let $K := \mathbb{Q}[\sqrt{-D}]$ be an imaginary quadratic field. Show that each ideal class of K has a unique fractional ideal $\mathfrak{a} = \mathbb{Z} + \mathbb{Z}z$ with $z \in F'$ for $F' = F^\circ \cup \{z \in F | \text{Re}(z) \geq 0\}$ for the interior F° of F .*

By sending $z \in F$ to $q := \exp(2\pi iz)$, $\{z \in F \mid \text{Im}(z) > 1\}$ is sent to an open disk of radius $\exp(-2\pi)$ punctured at the center $\mathbf{0}$. Thus by filling in $q^{-1}(\mathbf{0}) = \infty$, we find $\mathbf{P}^1(J) := \text{SL}_2(\mathbb{Z}) \backslash (\mathfrak{H} \cup \mathbf{P}^1(\mathbb{Q}))$ is (essentially a Riemann sphere).

For any subgroup of finite index Γ , we put $X(\Gamma) := \Gamma \backslash (\mathfrak{H} \cup \mathbf{P}^1(\mathbb{Q}))$ and $Y(\Gamma) := \Gamma \backslash \mathfrak{H}$. Then $X(\Gamma)$ is a finite covering of $\mathbf{P}^1(J)$ and hence $X(\Gamma)$ is a Riemann surface. If the image $\bar{\Gamma}$ does not have torsion, the topological fundamental group $\pi_1(Y(\Gamma))$ is isomorphic to $\bar{\Gamma}$. What happens if $\bar{\Gamma}$ has non-trivial torsion?

Exercise 2.8. Describe the local coordinate of $\mathbf{P}^1(J)$ around the image of a cubic root of unity in F .

Thus $Y_0(N) = \Gamma_0(N) \backslash \mathfrak{H}$ is an open Riemann surface with hole at cusps. In other words, $X_0(N) = \Gamma_0(N) \backslash (\mathfrak{H} \sqcup \mathbf{P}^1(\mathbb{Q}))$ is a compact Riemann surface.

Exercise 2.9. Show the following facts

- (1) $\text{SL}_2(K)$ acts transitively on $\mathbf{P}^1(K)$ for any field K by linear fractional transformation. Hint: $\begin{pmatrix} 1 & a \\ 0 & 1 \end{pmatrix} (0) = a$.
- (2) $\text{SL}_2(\mathbb{Z})$ acts transitively on $\mathbf{P}^1(\mathbb{Q})$.
- (3) Give an example of a number field K with an integer ring O such that $\text{SL}_2(O)$ does not act transitively on $\mathbf{P}^1(K)$.
- (4) $|X_0(N) - Y_0(N)| = 2$ if N is a prime.

2.2. Modular forms and q -expansions. Let $f : \mathfrak{H} \rightarrow \mathbb{C}$ be a holomorphic functions with $f(z+1) = f(z)$. Since $\mathfrak{H}/\mathbb{Z} \cong D = \{z \in \mathbb{C}^\times \mid |z| < 1\}$ by $z \mapsto q = \mathbf{e}(z) = \exp(2\pi iz)$, we may regard f as a function of q undefined at $q = 0 \Leftrightarrow z = i\infty$. Then the Laurent expansion of f gives

$$f(z) = \sum_n a(n, f) q^n = \sum_n a(n, f) \exp(2\pi in z).$$

In particular, we may assume that q is the coordinate of $X_0(N)$ around the infinity cusp ∞ . We call f is *finite* (resp. *vanishing*) at ∞ if $a(n, f) = 0$ if $n < 0$ (resp. if $n \leq 0$). By Exercise 2.9, we can bring any point $c \in \mathbf{P}^1(\mathbb{Q})$ to ∞ ; so, the coordinate around the cusp c is given by $q \circ \alpha$ for $\alpha \in \text{SL}_2(\mathbb{Q})$ with $\alpha(c) = \infty$.

Exercise 2.10. Show that the above α can be taken in $\text{SL}_2(\mathbb{Z})$. Hint: write $c = \frac{a}{b}$ as a reduced fraction; then, we can find $x, y \in \mathbb{Z}$ such that $ax - by = 1$.

We consider the space of holomorphic functions $f : \mathfrak{H} \rightarrow \mathbb{C}$ satisfying the following conditions for an even integer k :

(M1) $f\left(\frac{az+b}{cz+d}\right) = f(z)(cz+d)^k$ for all $\begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma_0(N)$.

If f satisfies the above conditions, we find that $f(z+1) = f(z)$ because $\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} (z) = z+1$; so, we can say that f is finite or not.

Exercise 2.11. Define $f| \begin{pmatrix} a & b \\ c & d \end{pmatrix} (z) = f\left(\frac{az+b}{cz+d}\right)(cz+d)^{-k}$. Prove the following facts:

- (1) $(f|\alpha)|\beta = f|(\alpha\beta)$ for $\alpha \in \text{SL}_2(\mathbb{R})$,
- (2) if f satisfies (M1), $f|\alpha$ satisfies (M1) replacing $\Gamma_0(N)$ by $\Gamma = \alpha^{-1}\Gamma_0(N)\alpha$,

(3) If $\alpha \in \mathrm{SL}_2(\mathbb{Z})$, show that Γ contains $\Gamma(N) = \{\gamma \in \mathrm{SL}_2(\mathbb{Z}) \mid \gamma - 1 \in NM_2(\mathbb{Z})\}$.

By (3) of the above exercise, for $\alpha \in \mathrm{SL}_2(\mathbb{Z})$, we find $f|\alpha(z + N) = f|\alpha(z)$; thus, $f|\alpha$ has expansion $f|\alpha = \sum_n a(n, f|\alpha)q^{Nn}$. We call f is finite (resp. vanishing) at the cusp $\alpha^{-1}(\infty)$ if $f|\alpha$ is finite (resp. vanishing) at ∞ . Consider the following condition:

(M2) f is finite at all cusps of $X_0(N)$.

We write $M_k(\Gamma_0(N))$ for the space of functions satisfying (M1–2). Replace (M2) by

(S) f is vanishing at all cusps of $X_0(N)$,

we define subspace $S_k(\Gamma_0(N)) \subset M_k(\Gamma_0(N))$ by imposing (S). Element in $S_k(\Gamma_0(N))$ is called a holomorphic cusp form on $\Gamma_0(N)$ of weight k .

Pick a Dirichlet character $\chi : (\mathbb{Z}/N\mathbb{Z})^\times \rightarrow \mathbb{C}^\times$. We impose slightly different conditions than (M1):

(M $_\chi$ 1) $f\left(\frac{az+b}{cz+d}\right) = \chi(d)f(z)(cz+d)^k$ for all $\begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma_0(N)$.

We write $M_k(\Gamma_0(N), \chi)$ for the space of holomorphic functions on \mathfrak{H} satisfying (M $_\chi$ 1) and (M2). If further we impose (S), the space will be written as $S_k(\Gamma_0(N), \chi)$.

2.3. Eisenstein series. Let $\chi : (\mathbb{Z}/N\mathbb{Z})^\times \rightarrow \overline{\mathbb{Q}}^\times$ be a primitive Dirichlet character. We consider the Eisenstein series of weight $0 < k \in \mathbb{Z}$

$$E'_{k,\chi}(z, s) = \sum_{(m,n) \in \mathbb{Z}^2 - \{(0,0)\}} \chi^{-1}(n)(mNz + n)^{-k} |mNz + n|^{-2s},$$

where $z \in \mathfrak{H}$ and $s \in \mathbb{C}$. When $N = 1$, χ is the trivial character **1**.

Since $\Gamma_\infty := \{\alpha \in \Gamma_0(N) \mid \alpha(\infty) = \infty\}$ is given by

$$\left\{ \pm \begin{pmatrix} 1 & m \\ 0 & 1 \end{pmatrix} \mid m \in \mathbb{Z} \right\},$$

we have

$$(2.1) \quad \Gamma_\infty \backslash \Gamma_0(N) \cong \{(cN, d) \in N\mathbb{Z} \times \mathbb{Z} \mid cN\mathbb{Z} + d\mathbb{Z} = \mathbb{Z}\} / \{\pm 1\}.$$

Exercise 2.12. Prove (2.1).

From this, we conclude

Lemma 2.13.

$$E'_{k,\chi}(z) = 2L(2s + k, \chi^{-1}) \sum_{\gamma \in \Gamma_\infty \backslash \Gamma_0(N)} \chi^{-1}(\gamma) j(\gamma, z)^{-k} |j(\gamma, z)|^{-2s},$$

where $\chi\left(\begin{pmatrix} a & b \\ c & d \end{pmatrix}\right) = \chi(d)$.

We put

$$E_{k,\chi}^* := \sum_{\gamma \in \Gamma_\infty \backslash \Gamma_0(N)} \chi^{-1}(\gamma) j(\gamma, z)^{-k} |j(\gamma, z)|^{-2s}.$$

Exercise 2.14. Prove the above lemma.

For the following exercise, see [MFM] Section 2.6 and Chapter 7.

Exercise 2.15. Prove

- (1) $E'_{k,\chi}(z, s)$ converges absolutely and locally uniformly with respect to $(z, s) \in \mathfrak{H} \times \mathbb{C}$ if $\operatorname{Re}(2s + k) > 2$;
- (2) $E'_{k,\chi}(z, s) = 0$ if $\chi(-1) \neq (-1)^k$ (assuming convergence);
- (3) $E'_{k,\chi}(z) = E'_{k,\chi}(z, 0)$ is a holomorphic function of z if $k > 2$ (this fact is actually true if $k = 2$ and $\chi \neq \mathbf{1}$ for the limit $E'_{k,\chi}(z) = \lim_{s \rightarrow +0} E'_{k,\chi}(z, s)$);
- (4) $E'_{k,\chi}(\gamma(z)) = \chi(d)(cz + d)^k E'_{k,\chi}(z)$ for $\gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma_0(N)$.

Recall that a holomorphic function $f : \mathfrak{H} \rightarrow \mathbb{C}$ is called a modular form on $\Gamma_0(N)$ of weight k with character χ if f satisfies the following conditions:

- (M $_{\chi}$ 1) $f\left(\frac{az+b}{cz+d}\right) = \chi(d)f(z)(cz + d)^k$ for all $\begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma_0(N)$;
- (M2) f is finite at all cusps of $X_0(N)$; in other words, for all $\alpha = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in SL_2(\mathbb{Z})$, $f|_k\alpha(z) = f(\alpha(z))(cz + d)^{-k}$ has Fourier expansion of the form

$$\sum_{0 \leq n \in N^{-1}\mathbb{Z}} a(n, f|_k\alpha) \exp(2\pi inz) \quad (\text{with } a(n, f|_k\alpha) \in \mathbb{C}).$$

Functions in the space $S_k(\Gamma_0(N), \chi)$ are called holomorphic cusp forms on $\Gamma_0(N)$ of weight k with character χ .

Exercise 2.16. Prove that $M_0(\Gamma_0(N), \chi)$ is either \mathbb{C} (constants) or 0 according as $\chi = \mathbf{1}$ or not.

Exercise 2.17. Prove that $M_k(\Gamma_0(N), \chi) = 0$ if $\chi(-1) \neq (-1)^k$.

Proposition 2.18. Let χ be a primitive Dirichlet character modulo N . The Eisenstein series $E'_{k,\chi}(z, s)$ for $0 < k \in \mathbb{Z}$ can be meromorphically continued as a function of s for a fixed z giving a real analytic function of z if $E'_{k,\chi}(z, s)$ is finite at $s \in \mathbb{C}$. If $\chi \neq \mathbf{1}$ or $k \neq 2$, $E'_{k,\chi}(z) = E'_{k,\chi}(z, 0)$ is an element in $M_k(\Gamma_0(N), \chi)$.

We only prove the last assertion for $k > 2$, since the proof of the other assertions require more preparation from real analysis. See [LFE] Chapter 9 (or [MFM] Chapter 7) for a proof of these assertions not proven here.

Proof. Suppose $k > 2$. Then $E'_{k,\chi}$ is absolutely and locally uniformly convergent by the exercise above, and hence $E'_{k,\chi}$ is a holomorphic functions in $z \in \mathfrak{H}$. Thus we need to compute its Fourier expansion. Since the computation is basically the same for all cusps, we only do the computation at the cusp ∞ . We use the following partial fraction expansion of cotangent function (can be found any advanced Calculus text or [LFE] (2.1.5-6) in page 28):

$$(2.2) \quad \begin{aligned} \pi \cot(\pi z) &= \pi i \frac{\exp(2\pi iz) + 1}{\exp(2\pi iz) - 1} = \frac{1}{z} + \sum_{n=1}^{\infty} \left(\frac{1}{z+n} + \frac{1}{z-n} \right) \\ \pi \cot(\pi z) &= \pi i \frac{\exp(2\pi iz) + 1}{\exp(2\pi iz) - 1} = \pi i \left(-1 - 2 \sum_{n=1}^{\infty} q^n \right), \quad q = \exp(2\pi iz). \end{aligned}$$

The two series converge locally uniformly on \mathfrak{H} and periodic on \mathbb{C} by definition. Applying the differential operator $(2\pi i)^{-1} \frac{\partial}{\partial z}$ to the formulas in (2.2) term by term, we get

$$(2.3) \quad S_k(z) = \sum_{n \in \mathbb{Z}} \frac{1}{(z+n)^k} = \frac{(-2\pi i)^k}{(k-1)!} \sum_{n=1}^{\infty} n^{k-1} q^n.$$

Form this, assuming $\chi(-1) = (-1)^k$, we have

$$(2.4) \quad \begin{aligned} E'_{k,\chi}(z) &= 2 \sum_{n=1}^{\infty} \chi(n)^{-1} n^{-k} + 2 \sum_{r=1}^N \chi^{-1}(r) \sum_{m=1}^{\infty} \sum_{n \in \mathbb{Z}} N^{-k} (mz + \frac{r}{N} + n)^{-k} \\ &= 2L(k, \chi^{-1}) + 2 \sum_{r=1}^N \chi^{-1}(r) \sum_{m=1}^{\infty} N^{-k} S_k(mz + \frac{r}{N}) \\ &\stackrel{(2.3)}{=} 2L(k, \chi^{-1}) + 2N^{-k} \frac{(-2\pi i)^k}{(k-1)!} \sum_{m=1}^{\infty} \sum_{n=1}^{\infty} n^{k-1} q^m \sum_{r=1}^N \chi^{-1}(r) \exp(2\pi i \frac{nr}{N}). \end{aligned}$$

By the functional equation (see [LFE] Theorem 2.3.2), we have, if $\chi(-1) = (-1)^k$,

$$(2.5) \quad L(k, \chi^{-1}) = G(\chi^{-1}) \frac{(-2\pi i)^k}{N^k (k-1)!} L(1-k, \chi),$$

where $G(\psi)$ for a primitive character ψ modulo C is the Gauss sum $\sum_{r=1}^C \psi(r) \exp(2\pi i \frac{r^2}{C})$.

We have $\sum_{r=1}^N \chi^{-1}(r) \exp(2\pi i \frac{nr}{N}) = \begin{cases} \chi(n)G(\chi^{-1}) & \text{if } n \text{ is prime to } N, \\ 0 & \text{otherwise,} \end{cases}$ and we get the formula

$$(2.6) \quad E'_{k,\chi}(z) = G(\chi^{-1}) \frac{2(-2\pi i)^k}{N^k (k-1)!} E_{k,\chi}(z)$$

for

$$E_{k,\chi}(z) = 2^{-1} L(1-k, \chi) + \sum_{n=1}^{\infty} \sigma_{k-1,\chi}(n) q^n$$

for $\sigma_{k-1,\chi}(n) = \sum_{0 < d|n} \chi(d) d^{k-1}$. Here we used the convention that $E_{k,\chi}(z) = 0$ if $\chi(-1) \neq (-1)^k$. \square

When $N = 1$ and $\chi = \mathbf{1}$ (the identity character), we simply write $\sigma_{k-1}(n)$ for $\sigma_{k-1,\chi}(n)$.

Exercise 2.19. Prove $\sigma_{k,\chi}(m)\sigma_{k,\chi}(n) = \sigma_{k,\chi}(mn)$ if $(m, n) = 1$ (i.e., m and n are co-prime). For a prime p , what is the relation between $\sigma_{k,\chi}(p)$ and $\sigma_{k,\chi}(p^2)$?

Exercise 2.20. Give a proof of

$$\sum_{r=1}^N \chi^{-1}(r) \exp(2\pi i \frac{nr}{N}) = \begin{cases} \chi(n)G(\chi^{-1}) & \text{if } n \text{ is prime to } N, \\ 0 & \text{otherwise.} \end{cases}$$

Exercise 2.21. Let p be a prime, and write $\mathbf{1}_p$ for the imprimitive identity character of $(\mathbb{Z}/p\mathbb{Z})^\times$. Prove that

$$E_{k,1}(z) - p^{k-1}E_{k,1}(pz) = 2^{-1}(1 - p^{k-1})\zeta(1 - k) + \sum_{n=1}^{\infty} \sigma_{k-1,1}^{(p)}(n)q^n$$

for $\sigma_{k-1,1}^{(p)}(n) = \sum_{0 < d|n, p \nmid n} d^{k-1}$. More generally, if N is prime to p , prove that

$$E_{k,\chi}(z) - \chi(p)p^{k-1}E_{k,\chi}(pz) = 2^{-1}(1 - \chi(p)p^{k-1})L(1 - k, \chi) + \sum_{n=1}^{\infty} \sigma_{k-1,\chi}^{(p)}(n)q^n$$

for $\sigma_{k-1,\chi}^{(p)}(n) = \sum_{0 < d|n, p \nmid n} \chi(d)d^{k-1}$.

3. EXPLICIT MODULAR FORMS OF LEVEL 1

3.1. Isomorphism classes of elliptic curves. An elliptic curve E (over \mathbb{C}) is a genus 1 Riemann surface with a specific point $\mathbf{0}$. By Weierstrass theory (cf. [GME, §2.4]) E can be embedded into the two dimensional projective space \mathbf{P}^2 and its image is defined as the zero set of cubic homogeneous equations (of the homogeneous coordinates of \mathbf{P}^2), it is called a curve (a dimension 1 algebraic variety). Since E has genus 1, its fundamental group $L := \pi_1(E, \mathbf{0})$ is a free module of rank 2 and is isomorphic to the homology group $H_1(E, \mathbb{Z})$. Therefore the universal covering of E is isomorphic to \mathbb{C} . In other words, $E \cong \mathbb{C}/L$ for a lattice $L = \mathbb{Z}w_1 + \mathbb{Z}w_2$ of \mathbb{C} . Then we may assume that $z = w_1/w_2 \in \mathfrak{H}$ (by interchanging w_i if necessary). The choice of the basis (w_1, w_2) is unique up to multiplication by $\mathrm{SL}_2(\mathbb{Z})$: $\begin{pmatrix} w_1 \\ w_2 \end{pmatrix} \mapsto \gamma \begin{pmatrix} w_1 \\ w_2 \end{pmatrix}$ for $\gamma \in \mathrm{SL}_2(\mathbb{Z})$. The isomorphism class of E is uniquely determined by (\mathbb{C}, L) up to scalar multiple. This multiplication induces the action $z \mapsto \gamma(z)$ on \mathfrak{H} , and z is uniquely determined by (w_1, w_2) modulo scalar multiplication. Thus we get

$$\{\text{elliptic curves}/_{\mathbb{C}}\} / \cong \leftrightarrow \mathrm{SL}_2(\mathbb{Z}) \backslash \mathfrak{H} = \mathbf{P}^1(J) - \{\infty\}.$$

Thus essentially modular forms of level 1 are functions of isomorphism classes of elliptic curves. Using this fact, we can make the theory of elliptic curves purely algebraically (see [GME, Chapter 3]), and hence we may regard the theory of modular forms as a part of algebraic number theory (though the original analytic definition due back to Gauss gives a foundation of the treatment of modular forms via analytic number theory).

3.2. Level 1 modular forms. We take $N = 1$ and $\chi = \mathbf{1}$ for the the construction of Eisenstein series. Put $\sigma_j(n) = \sum_{0 < d|n} d^j$ and

$$E_{2k} = 2^{-1}\zeta(1 - 2k) + \sum_{n=1}^{\infty} \sigma_{2k-1}(n)q^n \in M_{2k}(\mathrm{SL}_2(\mathbb{Z})).$$

Note that $\zeta(1 - 2k)$ for $k > 0$ is essentially a Bernoulli number and hence a rational number. Put

$$G_{2k} = 2\zeta(1 - 2k)^{-1}E_{2k} \in M_{2k}(\mathrm{SL}_2(\mathbb{Z})) \cap \mathbb{Q}[[q]].$$

Writing $G_{2k} = 1 + C_{2k} \sum_{n=1}^{\infty} \sigma_{2k-1}(n)q^n$, here is a table of C_k :

$2k$	4	6	8	10	14
C_{2k}	240	-504	480	-264	-24

Since $\zeta(-11) = \zeta(1-12) = \frac{691}{2^3 \cdot 3^2 \cdot 5 \cdot 7 \cdot 13}$, for $2k = 12$, G_{12} is not integral (and denominator is 691: Ramanujan's prime). Following the tradition from the time of Weierstrass, we define $g_2 = \frac{G_4}{12}$, $g_3 = \frac{G_6}{216}$ and $\Delta = g_2^3 - 27g_3^2 \in M_{12}(\text{SL}_2(\mathbb{Z}))$. Then the elliptic curve $E = \mathbb{C}/\mathbb{Z}z + \mathbb{Z}$ ($z \in \mathfrak{H}$) embedded by Weierstrass \wp -function ($u \mapsto (\wp(u) : \wp'(u) : 1)$) into \mathbf{P}^2 satisfies the equation

$$Y^2Z = 4X^3 - g_2(z)XZ^2 - g_3(z)Z^3.$$

Exercise 3.1. Explain why the curve defined by $Y^2Z = 4X^3 - g_2(z)XZ^2 - g_3(z)Z^3$ and $Y^2Z = 4X^3 - g_2(\gamma(z))XZ^2 - g_3(\gamma(z))Z^3$ for $\gamma \in \text{SL}_2(\mathbb{Z})$ are isomorphic in \mathbf{P}^2 .

The above equation gives a smooth curve if and only if the cubic equation $f_z(X) = 4X^3 - g_2(\gamma(z))X - g_3(z)$ has distinct three roots. Note that Δ is the discriminant of $f_z(X)$. Since $E = \mathbb{C}/L$ is smooth, we find $\Delta(z) \neq 0$ for all $z \in \mathfrak{H}$. On the other hand, the q -expansion of Δ is of the form

$$q + \sum_{n=2}^{\infty} \tau(n)q^n$$

by definition. Thus $\Delta(\infty) = 0$. This non-vanishing of Δ also follows from the following product q -expansion of Δ (e.g., [EEK, IV, (36)]):

$$\Delta = q \prod_{n=1}^{\infty} (1 - q^n)^{24} \in q\mathbb{Z}[[q]].$$

Ramanujan conjectured many things for Δ , for example,

- (1) $\tau(p)\tau(q) = \tau(pq)$ for primes $p \neq q$ (now a theorem of Mordell which we will prove),
- (2) $\tau(n) \equiv \sigma_{11}(n) \pmod{691}$ for all positive integer n (perhaps, first proven by Ribet in 1976 [R76], later we will give a proof).

Note here that the constant term of E_{12} is divisible by 691; so, we could write the last congruence in aggregate as $\Delta \equiv E_{12} \pmod{691}$ (or strictly speaking, $\Delta \equiv E_{12} \pmod{691\mathbb{Z}[[q]]}$). This is the first appearance in this course of congruence between modular forms. Note that Ribet proved that $p > k$ is a congruence prime (like 691 between a Hecke eigen cusp form and an Eisenstein series of the same weight k) if and only if the class group of $\mathbb{Q}(\mu_p)$ has a factor isomorphic to $\mathbb{Z}/p\mathbb{Z}$ on which $\text{Gal}(\mathbb{Q}(\mu_p)/\mathbb{Q})$ acts by the $(1-k)$ -th power of the Teichmüller character (a converse of Herbrand's theorem in early 20th century).

3.3. Dimension of $M_k(\text{SL}_2(\mathbb{Z}))$. Put $J = \frac{G_4^3}{\Delta}$. Since $\Delta \neq 0$ over \mathfrak{H} , J is holomorphic over \mathfrak{H} invariant under the action of $\text{SL}_2(\mathbb{Z})$. Thus J factors through $\text{SL}_2(\mathbb{Z}) \backslash \mathfrak{H}$. Since $\Delta = q + \sum_{n=1}^{\infty} \tau(n)q^n$ and $G_4 = 1 + C_4 \sum_{n=1}^{\infty} \sigma_3(n)q^n$, the function J has a pole of order 1 at ∞ . Thus we can take J as a coordinate of $\mathbf{P}^1(J) = \text{SL}_2(\mathbb{Z}) \backslash (\mathfrak{H} \sqcup \mathbf{P}^1(\mathbb{Q}))$. Here is a dimension formula for $M_k(\text{SL}_2(\mathbb{Z}))$:

Proposition 3.2. *We have for integers $k \geq 0$*

$$\dim M_{2k}(\mathrm{SL}_2(\mathbb{Z})) = \begin{cases} \left\lfloor \frac{k}{6} \right\rfloor + 1 & \text{if } k \not\equiv 1 \pmod{6} \text{ and } k \neq 1, \\ \left\lfloor \frac{k}{6} \right\rfloor & \text{if } k \equiv 1 \pmod{6}, \end{cases}$$

$$\dim S_{2k}(\mathrm{SL}_2(\mathbb{Z})) = \begin{cases} \left\lfloor \frac{k}{6} \right\rfloor & \text{if } k \not\equiv 1 \pmod{6}, \\ \left\lfloor \frac{k}{6} \right\rfloor - 1 & \text{if } k \equiv 1 \pmod{6}. \end{cases}$$

We also have $M_2(\mathrm{SL}_2(\mathbb{Z})) = 0$.

Here $[\alpha]$ is the integer with $\alpha - 1 < [\alpha] \leq \alpha$ for $\alpha \in \mathbb{Q}$. See [MFM, §2.5 and §4.2] for the dimension formula for general $M_k(\Gamma_0(N), \chi)$ and $S_k(\Gamma_0(N), \chi)$.

We prove some lemmas before proving the dimension formula. Write the right-hand-side of the dimension formula for $M_{2k}(\mathrm{SL}_2(\mathbb{Z}))$ above as $r(2k)$. Put $s(2k) = 2k - 12(r(2k) - 1)$.

Exercise 3.3. *Prove that the equation $4a + 6b = s(2k)$ has a unique non-negative integer solution for each integer k .*

Here is the list of the solutions:

$k \pmod{6}$	0	1	2	3	4	5
$s(2k)$	0	14	4	6	8	10
a	0	2	1	0	2	1
b	0	1	0	1	0	1

We now create an integral basis of $M_{2k}(\mathrm{SL}_2(\mathbb{Z}))$. Write $(a(k), b(k))$ for the unique non-negative integer solutions to $4a + 6b = s(2k)$. Then, following Y. Maeda, put

$$h_i = G_4^a G_6^{b+2(r(2k)-1-i)} \Delta^i \in M_{2k}(\mathrm{SL}_2(\mathbb{Z})) \cap \mathbb{Z}[[q]] \quad \text{for } i = 0, 1, 2, \dots, r(k).$$

Very special feature of $\{h_i\}_{0 \leq i \leq r(2k)-1}$ is

$$h_i = q^i + \sum_{n=i+1}^{\infty} a(i)_n q^n \in \mathbb{Z}[[q]].$$

In particular, they are linearly independent over \mathbb{Z} . Here is a corollary of this construction of the integral basis $\{h_i\}_i$:

Corollary 3.4. *Any $f \in M_{2k}(\mathrm{SL}_2(\mathbb{Z}))$ (resp. $g \in S_{2k}(\mathrm{SL}_2(\mathbb{Z}))$) is an integral linear combination of $\{h_i\}_{0 \leq i \leq r(2k)-1}$ (resp. $\{h_i\}_{1 \leq i \leq r(2k)-1}$).*

Write $S_k(\Gamma; A) = A[[q]] \cap S_{2k}(\Gamma)$ and $M_k(\Gamma; A) = A[[q]] \cap M_{2k}(\Gamma)$. We thus have

$$S_{2k}(\mathrm{SL}_2(\mathbb{Z}); \mathbb{Z}) = \sum_{i=1}^{r(k)-1} \mathbb{Z}h_i.$$

Here are some facts of the dimension 1 projective space.

- (1) $U_\infty := \mathbf{P}^1(\mathbb{C}) - \{\infty\} \cong \mathbb{C}$ (whose coordinate we write as t);
- (2) $U_0 := \mathbf{P}^1(\mathbb{C}) - \{0\} \cong \mathbb{C}$ whose coordinate is $u := t^{-1}$.

Let ω be a 1-differential form on $\mathbf{P}^1(\mathbb{C})$ holomorphic everywhere. Write $\omega = f(t)dt$ on U_∞ . If $f(t)$ is bounded over $U_\infty = \mathbb{C}$, it has to be constant. Then ω has to have a pole at ∞ as $dt = -u^{-2}du$. Thus $\omega = 0$. In other words,

$$H^0(\mathbf{P}^1(\mathbb{C}), \Omega_{\mathbf{P}^1(\mathbb{C})/\mathbb{C}}) = 0.$$

If ω is holomorphic over U_∞ and have a pole of order 1 at ∞ , then $\omega = -f(u)u^{-2}du$ has order 1-pole. This is possible if $f(u) = a_1u + \sum_{n=2}^\infty a_nu^n$. In other words, $|f(u)|$ is bounded over U_0 ; so, f is a constant. Then $\omega = 0$ again. Thus writing $\Omega_{\mathbf{P}^1(\mathbb{C})/\mathbb{C}}(-\infty)$ for the sheaf of differentials having pole only at ∞ of order ≤ 1 , we have

$$H^0(\mathbf{P}^1(\mathbb{C}), \Omega_{\mathbf{P}^1(\mathbb{C})/\mathbb{C}}(-\infty)) = 0,$$

which implies $M_2(\mathrm{SL}_2(\mathbb{Z})) = 0$ as

$$M_2(\mathrm{SL}_2(\mathbb{Z})) \ni f \mapsto f(z)dz \in H^0(\mathbf{P}^1(\mathbb{C}), \Omega_{\mathbf{P}^1(\mathbb{C})/\mathbb{C}}(-\infty)) = 0.$$

Thus to prove Proposition 3.2, we need to show that

$$\dim M_{2k}(\mathrm{SL}_2(\mathbb{Z})) \leq r(2k)$$

for $k \neq 1$.

Proof of Proposition 3.2. Suppose $k \neq 1$. Consider

$$T_k = G_{14-s(2k)}\Delta^{-r(2k)} = c_{k,-r(2k)}q^{-r(2k)} + \cdots + c_{k,0} + \sum_{n=1}^\infty c_{k,n}q^n \in \mathbb{Z}((q)).$$

Note that $c_{k,-r(2k)} = 1$. The weight of T_k is given by $14 - s(2k) - 12r(2k) = 2 - 2k$. In particular, for each $f \in M_{2k}(\mathrm{SL}_2(\mathbb{Z}))$, fT_k has weight 2. Since $d\gamma(z) = j(\gamma, z)^{-2}dz$ for $j\left(\begin{pmatrix} a & b \\ c & d \end{pmatrix}, z\right) = cz + d$ for $\gamma \in \mathrm{SL}_2(\mathbb{R})$, $\omega(f) = (2\pi i)fT_k dz = f(q)T_k(q)dq/q$ is a 1-differential holomorphic over $U_\infty \subset \mathbf{P}^1(J)$. It has pole of order $r(2k) + 1$ at ∞ (as $dq/q = 2\pi idz$).

Put $\omega_m = J^m dJ$. Then ω_m is holomorphic over U_∞ and has a pole of order $m + 2$ at ∞ . Write $\omega_m = c_{-m-2}q^{-m-2} + \cdots + c_{-1}q^{-1} + \cdots$. Note that c_{-m-2} is not zero. Expanding $\omega(f) = (b_{-r(2k)}q^{-r(2k)-1} + \cdots + b_{-1}q^{-1} + \sum_{n=0}^\infty b_nq^n)dq$, we find $\omega(f) - \frac{b_{-r(2k)}}{c_{-r(2k)-1}}\omega_{r(2k)-1}$ is holomorphic over U_∞ and has a pole of order at most $r(2k) - 2$. Replacing $\omega(f)$ by $\omega(f) - \frac{b_{-r(2k)}}{c_{-r(2k)-1}}\omega_{r(2k)-1}$ and repeating taking off suitable multiple of ω_j ($j = 0, \dots, r(2k) - 1$), we find that $\omega(f) - a_0\omega_0 - \cdots - a_{r(2k)+2}\omega_{r(2k)}$ is holomorphic over U_∞ and has a pole at ∞ of order at most 1. Since $H^0(\mathbf{P}^1(\mathbb{C}), \Omega_{\mathbf{P}^1(\mathbb{C})/\mathbb{C}}(-\infty)) = 0$, we see that $\omega(f)$ is linear combination of $\omega_0, \dots, \omega_{r(2k)-1}$. This shows $\dim M_{2k}(\mathrm{SL}_2(\mathbb{Z})) \leq r(2k)$, which finishes the proof. \square

For a subring A of \mathbb{C} , we put

$$M_{2k}(\mathrm{SL}_2(\mathbb{Z}); A) = M_{2k}(\mathrm{SL}_2(\mathbb{Z})) \cap A[[q]] \quad \text{and} \quad S_{2k}(\mathrm{SL}_2(\mathbb{Z}); A) = S_{2k}(\mathrm{SL}_2(\mathbb{Z})) \cap A[[q]].$$

Corollary 3.5. *We have $M_{2k}(\mathrm{SL}_2(\mathbb{Z}); A) = M_{2k}(\mathrm{SL}_2(\mathbb{Z}); \mathbb{Z}) \otimes_{\mathbb{Z}} A$ and $S_{2k}(\mathrm{SL}_2(\mathbb{Z}); A) = S_{2k}(\mathrm{SL}_2(\mathbb{Z}); \mathbb{Z}) \otimes_{\mathbb{Z}} A$. Moreover $\{g_2^a g_3^b \mid 4a + 6b = 2k, 0 \leq a, b \in \mathbb{Z}\}$ is a basis of $M_{2k}(\mathrm{SL}_2(\mathbb{Z}); \mathbb{Z}[\frac{1}{6}])$.*

We quote the following celebrated result of Siegel (see [LFE, §5.2]):

Corollary 3.6. *Let $c_{k,-j}$ ($j = 0, \dots, r(2k)$) be the coefficients of T_k . Then for any $f = \sum_{n=0}^{\infty} a_n q^n \in M_{2k}(\mathrm{SL}_2(\mathbb{Z}))$, we have $c_{k,0}a_0 + c_{k,-1}a_1 + \dots + c_{k,-r(2k)}a_{r(2k)} = 0$ and $c_{k,0} \neq 0$.*

Proof. Note that $\omega_m = J^m dJ = \frac{1}{m+1} \frac{dJ^m}{dq} dq$ does not have the term q^{-1} . Thus $\omega(f)$ neither. The coefficient of q^{-1} of $\omega(f)$ is given by $c_{k,0}a_0 + c_{k,-1}a_1 + \dots + c_{k,-r(2k)}a_{r(2k)}$. We have $c_{k,-r(2k)} = 1$. For Siegel's proof of non-vanishing of $c_{k,0}$, see [S69] and [LFE, §5.2], though this is an easy computational exercise. \square

For any totally real field F , Siegel then created a rational modular form of weight $2k[F : \mathbb{Q}]$ such that the constant term is $\zeta_F(1 - 2k)$. Then the above corollary implies $\zeta_F(1 - 2k) \in \mathbb{Q}$ for all $0 < k \in \mathbb{Z}$ (a generalization of Euler's rationality of $\zeta(1 - 2k)$ after more than 200 years). Here is a table (computed by Siegel) of Siegel numbers $c_{k,j}$:

$2k$	$c_{k,0}$	$c_{k,-1}$	$c_{k,-2}$
4	$-240 (-2^4 \cdot 3 \cdot 5)$	1	
6	$504 (2^3 \cdot 3^2 \cdot 7)$	1	
8	$-480 (-2^5 \cdot 3 \cdot 5)$	1	
10	$264 (2^3 \cdot 3 \cdot 11)$	1	
12	$-196560 (-2^4 \cdot 3^3 \cdot 5 \cdot 7 \cdot 13)$	$24 (2^3 \cdot 3)$	1
14	$24(2^3 \cdot 3)$	1	

4. HECKE OPERATORS

Let $GL_2^+(\mathbb{R}) = \{\alpha \in GL_2(\mathbb{R}) \mid \det(\alpha) > 0\}$ and put $GL_2^+(A) = GL_2^+(\mathbb{R}) \cap GL_2(A)$ for $A \subset \mathbb{R}$. For $\alpha = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in GL_2^+(\mathbb{R})$ and a function $f : \mathfrak{H} \rightarrow \mathbb{C}$, we define $f|\alpha(z) = \det(\alpha)^{k-1} f(\alpha(z))(cz + d)^{-k}$ if $\alpha = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$.

Exercise 4.1. *Prove $(f|\alpha)|\beta = f|(\alpha\beta)$ for $\alpha, \beta \in GL_2^+(\mathbb{R})$.*

Then $f \in S_k(\Gamma_0(N))$ (resp. $f \in M_k(\Gamma_0(N))$) if and only if f vanishes (resp. finite) at all cusps of $X_0(N)$ and $f|\gamma = f$ for all $\gamma \in \Gamma_0(N)$. Let $\Gamma = \Gamma_0(N)$. For $\alpha \in GL_2(\mathbb{R})$ with $\det(\alpha) > 0$, if $\Gamma\alpha\Gamma$ can be decomposed into a disjoint union of finite left cosets $\Gamma\alpha\Gamma = \bigsqcup_{j=1}^h \Gamma\alpha_j$, we can think of the finite sum $g = \sum_j f|\alpha_j$. If $\gamma \in \Gamma$, then $\alpha_j\gamma \in \Gamma\alpha_{\sigma(j)}$ for a unique index $1 \leq \sigma(j) \leq h$ and σ is a permutation of $1, 2, \dots, h$. If further, $f|\gamma = f$ for all $\gamma \in \Gamma$, we have

$$g|\gamma = \sum_j f|\alpha_j\gamma = \sum_j f|\gamma_j\alpha_{\sigma(j)} = \sum_j (f|\gamma_j)|\alpha_{\sigma(j)} = \sum_j f|\alpha_{\sigma(j)} = g.$$

Thus under the condition that $f|\gamma = f$ for all $\gamma \in \Gamma$, $f \mapsto g$ is a linear operator only dependent on the double coset $\Gamma\alpha\Gamma$; so, we write $g = f|[\Gamma\alpha\Gamma]$. More generally, if we

have a set $T \subset GL_2^+(\mathbb{R})$ such that $\Gamma T \Gamma = T$ with finite $|\Gamma \backslash T|$, we can define the operator $[T]$ acting on $M_k(\Gamma_0(N))$ by $f \mapsto \sum_j f|t_j$ if $T = \bigsqcup_j \Gamma t_j$. We define

$$\Delta_0(N) = \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in M_2(\mathbb{Z}) \cap GL_2^+(\mathbb{R}) \mid c \equiv 0 \pmod{N}, a\mathbb{Z} + N\mathbb{Z} = \mathbb{Z} \right\}.$$

Exercise 4.2. Prove that $\Gamma \Delta_0(N) \Gamma = \Delta_0(N)$ for $\Gamma = \Gamma_0(N)$.

Remark 4.1. For a character $\chi : (\mathbb{Z}/N\mathbb{Z})^\times \rightarrow \mathbb{C}^\times$ and $\alpha \in \Delta_0(N)$, we define $f|_\chi \alpha(z) = \det(\alpha)^{k-1} \chi(a) f(\alpha(z)) (cz + d)^{-k}$ if $\alpha = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$. Then, if $T \subset \Delta_0(N)$ with $\Gamma_0(N) T \Gamma_0(N)$ with finite $|\Gamma_0(N) \backslash T|$, we can define $[T] : M_k(\Gamma_0(N), \chi) \rightarrow M_k(\Gamma_0(N), \chi)$ by $f|[T] = \sum_j f|_\chi t_j$.

Lemma 4.3. Let $\Gamma = \Gamma_0(N)$.

- (1) If $\alpha \in M_2(\mathbb{Z})$ with positive determinant, $|\Gamma \backslash (\Gamma \alpha \Gamma)| < \infty$;
- (2) If p is a prime,

$$\Gamma \begin{pmatrix} 1 & 0 \\ 0 & p \end{pmatrix} \Gamma = \left\{ \alpha \in \Delta_0(N) \mid \det(\alpha) = p \right\} = \begin{cases} \Gamma \begin{pmatrix} p & 0 \\ 0 & 1 \end{pmatrix} \sqcup \bigsqcup_{j=0}^{p-1} \Gamma \begin{pmatrix} 1 & j \\ 0 & p \end{pmatrix} & \text{if } p \nmid N, \\ \bigsqcup_{j=0}^{p-1} \Gamma \begin{pmatrix} 1 & j \\ 0 & p \end{pmatrix} & \text{if } p \mid N. \end{cases}$$

- (3) for an integer $n > 0$,

$$\begin{aligned} T_n &:= \left\{ \alpha \in \Delta_0(N) \mid \det(\alpha) = n \right\} \\ &= \bigsqcup_a \bigsqcup_{b=0}^{d-1} \Gamma_0(N) \begin{pmatrix} a & b \\ 0 & d \end{pmatrix} \quad (a > 0, ad = n, (a, N) = 1, a, b, d \in \mathbb{Z}), \end{aligned}$$

- (4) Write $T(n)$ for the operator corresponding to T_n . Then we get the following identity of Hecke operators for $f \in M_k(\Gamma_0(N), \chi)$:

$$a(m, f|T(n)) = \sum_{0 < d \mid (m, n), (d, N) = 1} \chi(d) d^{k-1} \cdot a\left(\frac{mn}{d^2}, f\right).$$

- (5) $T(m)T(n) = T(n)T(m)$ for all integers m and n , and $T(m)T(n) = T(mn)$ as long as m and n are co-prime.

Proof. For simplicity, we assume $\chi = \mathbf{1}$. Note that (1) and (2) are particular cases of (3). We only prove (2), (4) when $n = p$ for a prime p and (5), leaving the other cases as an exercise (see [IAT] Proposition 3.36 and and (3.5.10) for a detailed proof of (3) and (4)).

We first deal with (2). Since the argument in each case is essentially the same, we only deal with the case where $p \nmid N$ and $\Gamma = \Gamma_0(N)$. Take any $\gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in M_2(\mathbb{Z})$ and $ad - bc = p$. If c is divisible by p , then ad is divisible by p ; so, one of a and d has a factor p . We then have

$$\gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} = \begin{pmatrix} a/p & b \\ c/p & d \end{pmatrix} \begin{pmatrix} p & 0 \\ 0 & 1 \end{pmatrix} \in \Gamma_0(N) \begin{pmatrix} p & 0 \\ 0 & 1 \end{pmatrix}$$

if a is divisible by p . If d is divisible by p and a is prime to p , choosing an integer j with $0 \leq j \leq p-1$ with $ja \equiv b \pmod{p}$, we have $\gamma \begin{pmatrix} 1 & j \\ 0 & p \end{pmatrix}^{-1} \in GL_2(\mathbb{Z})$. If c is not divisible by

p but a is divisible by p , we can interchange a and c via multiplication by $\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$ from the left-side. If a and c are not divisible by p , choosing an integer j so that $ja \equiv -c \pmod{p}$, we find that the lower left corner of $\begin{pmatrix} 1 & 0 \\ j & 1 \end{pmatrix} \gamma$ is equal to $ja + c$ and is divisible by p . This finishes the proof of (2).

We now deal with (4) assuming $n = p$. By (2), we have

$$(4.1) \quad f|T(p)(z) = \begin{cases} p^{k-1} \cdot f(pz) + \sum_{j=0}^{p-1} f\left(\frac{z+j}{p}\right) & \text{if } p \nmid N, \\ \sum_{j=0}^{p-1} f\left(\frac{z+j}{p}\right) & \text{if } p|N. \end{cases}$$

Writing $f = \sum_{n=1}^{\infty} a(n, f)q^n$ for $q = \mathbf{e}(z)$, we find

$$a(m, f|T(p)) = a(mp, f) + p^{k-1} \cdot a\left(\frac{m}{p}, f\right).$$

Here we put $a(r, f) = 0$ unless r is a non-negative integer.

The formula of Lemma 4.3 (4) is symmetric with respect to m and n ; so, we conclude $T(m)T(n) = T(n)T(m)$. From (4), it is plain that $T(m)T(n) = T(mn)$ if $(m, n) = 1$. This proves (5). \square

Exercise 4.4. Give a detailed proof of the above lemma.

The following exercise is more difficult:

Exercise 4.5. Let $\Gamma = \mathrm{SL}_2(\mathbb{Z})$. Prove that $|\Gamma \backslash (\Gamma \alpha \Gamma)| < \infty$ for $\alpha \in \mathrm{GL}_2(\mathbb{R})$ if and only if $\alpha \in \mathrm{GL}_2(\mathbb{Q})$ modulo real scalar matrices.

4.1. **Duality.** Let $A \subset \mathbb{C}$ be a subring, and define

$$S_k(\Gamma_0(N), A) = \{f \in S_k(\Gamma_0(N)) \mid a(n, f) \in A\}.$$

By definition, $S_k(\Gamma_0(N), \mathbb{C}) = S_k(\Gamma_0(N))$. We admit the following fact proven by Shimura in 1950s:

Theorem 4.6. If A is a subring of \mathbb{C} , we have

$$S_k(\Gamma_0(N), A) = S_k(\Gamma_0(N), \mathbb{Z}) \otimes_{\mathbb{Z}} A.$$

We proved this when $N = 1$ (see Corollary 3.5) and we include some explanation later. For any commutative algebra, we define $S_k(\Gamma_0(N); A) = S_k(\Gamma_0(N); \mathbb{Z}) \otimes_{\mathbb{Z}} A$. Letting $\mathbb{Z}[\chi]$ be the subalgebra of $\overline{\mathbb{Q}}$ generated by the values of Dirichlet character χ modulo N , the same formula $S_k(\Gamma_0(N), \chi; A) = S_k(\Gamma_0(N), \chi; \mathbb{Z}[\chi]) \otimes_{\mathbb{Z}[\chi]} A$ holds true for any $\mathbb{Z}[\chi]$ -algebra $A \subset \mathbb{C}$.

We let $T(n)$ acts on $S_k(\Gamma_0(N); A)$ by the formula Lemma 4.3 (4). Define

$$(4.2) \quad \begin{aligned} h_k(N; A) &= A[T(n) \mid n = 1, 2, \dots] \subset \mathrm{End}_A(S_k(\Gamma_0(N); A)), \\ H_k(N; A) &= A[T(n) \mid n = 1, 2, \dots] \subset \mathrm{End}_A(M_k(\Gamma_0(N); A)) \end{aligned}$$

and call $h_k(N; A)$ the Hecke algebra on $\Gamma_0(N)$. Replacing $S_k(\Gamma_0(N))$ (resp. $M_k(\Gamma_0(N))$) by $S_k(\Gamma_0(N), \chi; \mathbb{C})$ (resp. $M_k(\Gamma_0(N), \chi; \mathbb{C})$) in the above formula, we can define for any $\mathbb{Z}[\chi]$ -algebra A , the Hecke algebras $h_k(N, \chi; A)$ (resp. $H_k(N, \chi; A)$). By Lemma 4.3 (5), $h_k(N; A)$ is a commutative A -algebra.

We define an A -bilinear pairing

$$\langle \cdot, \cdot \rangle : h_k(N, \chi; A) \times S_k(\Gamma_0(N), \chi; A) \rightarrow A$$

by $\langle h, f \rangle = a(1, f|h)$.

Proposition 4.7. *We have the following canonical isomorphism:*

$\text{Hom}_A(S_k(\Gamma_0(N), \chi; A), A) \cong h_k(N, \chi; A)$ and $\text{Hom}_A(h_k(N, \chi; A), A) \cong S_k(\Gamma_0(N), \chi; A)$, and the latter is given by sending an A -linear form $\phi : h_k(N, \chi; A) \rightarrow A$ to the q -expansion $\sum_{n=1}^{\infty} \phi(T(n))q^n$.

Since the proof is the same, we only prove this result for $\chi = \mathbf{1}$.

Proof. We start with proving the result for a subfield A of \mathbb{C} . Since $h_k(N; \mathbb{C})$ and $S_k(\Gamma_0(N), \mathbb{C})$ are both finite dimensional, we only need to show the non-degeneracy of the pairing. By Lemma 4.3 (4), we find $\langle T(n), f \rangle = a(n, f)$; so, if $\langle h, f \rangle = 0$ for all n , we find $f = 0$. If $\langle h, f \rangle = 0$ for all f , we find

$$0 = \langle h, f|T(n) \rangle = a(1, f|T(n)h) = a(1, f|hT(n)) = \langle T(n), f|h \rangle = a(n, f|h).$$

Thus $f|h = 0$ for all f , implying $h = 0$ as an operator.

By Theorem 4.6, we have

$$S_k(\Gamma_0(N), \mathbb{Z}) \otimes_{\mathbb{Z}} \mathbb{C} = S_k(\Gamma_0(N)),$$

and therefore

$$S_k(\Gamma_0(N), \mathbb{Z}) \otimes_{\mathbb{Z}} A = S_k(\Gamma_0(N), A)$$

for any ring A . In particular, $h_k(N; A)$ is a subalgebra of $\text{End}_{\mathbb{C}}(S_k(\Gamma_0(N)))$ generated over A by $T(n)$ for all n . Then by definition $h_k(N; A) = h_k(N; \mathbb{Z}) \otimes_{\mathbb{Z}} A$ for any subring $A \subset \mathbb{C}$.

As for $A = \mathbb{Z}$, we only need to show that $\phi \mapsto \sum_{n=1}^{\infty} \phi(T(n))q^n$ is well defined and is surjective onto $S_k(\Gamma_0(N), \mathbb{Z})$ from $h_k(N; \mathbb{Z})$, because this is the case if we extend scalar to $A = \mathbb{Q}$. The cusp form $f \in S_k(\Gamma_0(N), A)$ corresponding to ϕ satisfies $\langle h, f \rangle = \phi(h)$; so, $a(n, f) = \langle T(n), f \rangle = \phi(T(n))$. Thus $f = \sum_{n=1}^{\infty} \phi(T(n))q^n \in S_k(\Gamma_0(N), A)$. However

$$f \in S_k(\Gamma_0(N), \mathbb{Z}) \iff \phi \in \text{Hom}(h_k(N; \mathbb{Z}), \mathbb{Z}),$$

because $h_k(N; \mathbb{Z})$ is generated by $T(n)$ over \mathbb{Z} . This is enough to conclude surjectivity.

Since $h_k(N; A) = h_k(N; \mathbb{Z}) \otimes A$ and $S_k(\Gamma_0(N), \mathbb{Z}) \otimes_{\mathbb{Z}} A = S_k(\Gamma_0(N), A)$, the duality over \mathbb{Z} implies that over A . \square

Corollary 4.8. *We have the following assertions.*

- (1) *For any \mathbb{C} -algebra homomorphism $\lambda : h_k(N; \mathbb{C}) \rightarrow \mathbb{C}$, $\lambda(h_k(N; \mathbb{Z}))$ is in the integer ring of an algebraic number field. In other words, $\lambda(T(n))$ for all n generates an algebraic number field $\mathbb{Q}(\lambda)$ over \mathbb{Q} and $\lambda(T(n))$ is an algebraic integer.*

(2) For any \mathbb{Z} -algebra homomorphism $\lambda : h_k(N; \mathbb{Z}) \rightarrow \mathbb{Q}(\lambda)$,

$$S_k(\Gamma_0(N), \mathbb{Q}(\lambda))[\lambda] = \{f \in S_k(\Gamma_0(N), \mathbb{Q}(\lambda)) \mid f|T(n) = \lambda(T(n))f \text{ for all } n\}$$

is one dimensional and is generated by $f_\lambda := \sum_{n=1}^{\infty} \lambda(T(n))q^n$.

Proof. Since $h_k(N; \mathbb{Z})$ is of finite rank over \mathbb{Z} , $R = \lambda(h_k(N; \mathbb{Z}))$ has finite rank d over \mathbb{Z} . Then the characteristic polynomial $P(X)$ of multiplication by $r \in R$ (regarding $R \cong \mathbb{Z}^d$) is satisfied by r , that is, $P(r) = 0$. Since $P(X) \in \mathbb{Z}[X]$, r is an algebraic integer. Then $R \otimes_{\mathbb{Z}} \mathbb{Q}$ is a finite extension $\mathbb{Q}(\lambda)$ of degree d over \mathbb{Q} .

Let K be a field. For any finite dimensional commutative K -algebra A , a K -algebra homomorphism $\lambda : A \rightarrow K$ gives rise to a generator of λ -eigenspace of the linear dual $\text{Hom}_K(A, K)$. Applying this fact to $\text{Hom}_K(h_k(N; \mathbb{Z}), K) = S_k(\Gamma_0(N), K)$ for $K = \mathbb{Q}(\lambda)$, we get the second assertion. \square

Corollary 4.9. *Let $r = r(2k) = \dim S_{2k}(\text{SL}_2(\mathbb{Z}))$. Then $T(1), T(2), \dots, T(r)$ gives a basis of $h_{2k}(1; \mathbb{Z})$ over \mathbb{Z} .*

Perhaps, except for the case of $N = 1$ above, no known explicit basis of $h_k(N; \mathbb{Z})$ over \mathbb{Z} .

Proof. Out of the basis h_1, \dots, h_r we created in Corollary 3.4, we get a basis g_i such that $\langle T(i), g_j \rangle = a(i, g_j) = \delta_{ij}$ for $1 \leq i, j \leq r$. Thus $T(1), \dots, T(r)$ is the dual basis of $\{g_j\}_j$ of $h_{2k}(1; \mathbb{Z})$. \square

Look at Lemma 4.3 (4) again:

$$a(m, f|T(n)) = \sum_{0 < d \mid (m, n), (d, N) = 1} \chi(d)d^{k-1} \cdot a\left(\frac{mn}{d^2}, f\right).$$

We see

$$\begin{aligned} \langle T(m)T(n), f \rangle &= \langle T(m), f|T(n) \rangle = a(m, f|T(n)) = \\ &= \sum_{0 < d \mid (m, n), (d, N) = 1} \chi(d)d^{k-1} \cdot \langle T\left(\frac{mn}{d^2}\right), f \rangle = \left\langle \sum_{0 < d \mid (m, n), (d, N) = 1} \chi(d)d^{k-1} \cdot T\left(\frac{mn}{d^2}\right), f \right\rangle \end{aligned}$$

for all f . Thus we conclude

Lemma 4.10. *For any pair of positive integers m, n , we have*

$$T(m)T(n) = \sum_{0 < d \mid (m, n), (d, N) = 1} \chi(d)d^{k-1} \cdot T\left(\frac{mn}{d^2}\right).$$

In particular, for a prime $p \nmid N$, if $m \geq n$,

$$T(p^m)T(p^n) = \sum_{j=0}^n \chi(p)^j d^{(k-1)j} \cdot T(p^{m+n-2j}),$$

and if $p \mid N$, $T(p^n) = T(p)^n$.

Because of difference of the formula above for $p \nmid N$ and $p|N$, we often write $U(p)$ for $T(p)$ if $p|N$.

Suppose $p \nmid N$. Let A, B be the root of $X^2 - T(p)X + \chi(p)p^{k-1}$. Then $T(p) = A + B$ and $\chi(p)p^{k-1} = AB$. Taking $m = n = 1$ in the above lemma, the formula

$$T(p^m)T(p^n) = \sum_{j=0}^m \chi(p)^j d^{(k-1)j} \cdot T(p^{m+n-2j}),$$

becomes $T(p)^2 = T(p^2) + \chi(p)d^{k-1}$; so, $T(p^2) = (A + B)^2 - AB = A^2 + AB + B^2$, Inductively, we then get

Corollary 4.11. *Let the notation be as above. We have $AB = \chi(p)p^{k-1}$ and*

$$T(p^n) = A^n + A^{n-1}B + \dots + AB^{n-1} + B^n = \text{Tr}\left(\begin{pmatrix} A & 0 \\ 0 & B \end{pmatrix}^{sym \otimes n}\right)$$

for all $n > 0$.

4.2. Congruences among cusp forms. As we will see later, $h_{2k}(1; \mathbb{Q})$ is semi-simple, and $h_{2k}(1; \mathbb{Z})$ is an order of $h_{2k}(1; \mathbb{Z})$ (i.e., a subring and is a lattice). Thus the discriminant of $h_{2k}(1; \mathbb{Z})$ is well defined and given by $D(2k) := \det(\text{Tr}(T(i)T(j)))_{1 \leq i, j \leq r(2k)}$. The trace $\text{Tr}(T(i)T(j))$ can be computed by the trace formula (cf. [MFM, §6.8]).

Primes appearing in the discriminant of the Hecke algebra gives congruence among algebra homomorphisms of the Hecke algebra into $\overline{\mathbb{Q}}$. For the small even weights $k = 26, 22, 20, 18, 16, 12$, we have $\dim_{\mathbb{C}} S_k(SL_2(\mathbb{Z})) = 1$, and the Hecke field $h_k(1; \mathbb{Z}) = \mathbb{Z}$ and hence the discriminant is 1. As is well known from the time of Hecke that

$$h_{24}(1; \mathbb{Z}) \otimes_{\mathbb{Z}} \mathbb{Q} = \mathbb{Q}[\sqrt{144169}].$$

Thus $S_{24}(SL_2(\mathbb{Z})) = \mathbb{C}f + \mathbb{C}g$ for two Hecke eigenforms f, g Galois conjugate each other with coefficients in $\mathbb{Q}[\sqrt{144169}]$ such that $f \equiv g \pmod{(\sqrt{144169})}$. Here is a table by Y. Maeda of the discriminant of the Hecke algebra of weight k for $S_k(SL_2(\mathbb{Z}))$ when $\dim S_k(SL_2(\mathbb{Z})) = 2$:

Discriminant of Hecke algebras.

weight	dim	Discriminant
24	2	$2^6 \cdot 3^2 \cdot 144169$
28	2	$2^6 \cdot 3^6 \cdot 131 \cdot 139$
30	2	$2^{12} \cdot 3^2 \cdot 51349$
32	2	$2^6 \cdot 3^2 \cdot 67 \cdot 273067$
34	2	$2^8 \cdot 3^4 \cdot 479 \cdot 4919$
38	2	$2^{10} \cdot 3^2 \cdot 181 \cdot 349 \cdot 1009$

The occurrence of many congruences between non Galois conjugates are first remarked by Doi and Ohta [DO77]. If we find two Hecke eigenforms f, g in $S_k(\Gamma_0(N))$ with $f \equiv g \pmod{\mathfrak{P}}$ for a prime \mathfrak{P} in $\overline{\mathbb{Q}}$, we call $(p) = \mathfrak{P} \cap \mathbb{Z}$ a congruence prime for f and g . In the following table, if we write 1 + 2 for splitting if $h_k^-(p; \mathbb{Q}) = \mathbb{Q} \oplus K$ for $[K : \mathbb{Q}] = 2$. Here the sign “-” as the superscript of the Hecke algebra means the following. The normalizer $\Gamma_0^*(p)$ of $\Gamma_0(p)$ for a prime is generated by Weil involution $\begin{pmatrix} 0 & -1 \\ p & 0 \end{pmatrix}$ which acts

by \pm on $S_2(\Gamma_0(p))$. The algebra $h_k^-(p; \mathbb{Q})$ is the subalgebra generated over \mathbb{Q} by Hecke operators acting on the “ $-$ ” eigenspace.

level p	splitting	congruence prime
67	$1 + 2$	5
151	$3 + 6$	2, 67
199	$2 + 10$	71
211	$2 + 9$	41

We ask

Problem 4.12. *What are these congruence primes? Is there any formula to give the congruence primes? Do congruence primes have some arithmetic meaning?*

In this course and the 205c course in Spring 2017, we try to give an answer to this question.

Exercise 4.13. *Prove that the matrix $\tau = \begin{pmatrix} 0 & -1 \\ N & 0 \end{pmatrix}$ normalizes $\Gamma_0(N)$. Moreover prove that if N is square free, the normalizer $\mathcal{N}(\Gamma_0(N))$ in $\mathrm{SL}_2(\mathbb{R})$ contains $\Gamma_0(N)$ as a subgroup of index 2^r for the number r of primes dividing N and that $\mathcal{N}(\Gamma_0(N))/\Gamma_0(N)$ is a $(2, 2, \dots, 2)$ group.*

We define the Weil involution $W = W_N$ by

$$f|W = N^{k/2} f(\tau(z)) j(\tau, z)^{-k}$$

on $S_k(\Gamma_0(N), \chi)$. Note that $W^2 = (-1)^k$ and $W : S_k(\Gamma_0(N), \chi) \rightarrow S_k(\Gamma_0(N), \chi^{-1})$. Moreover, if f_λ is primitive in the sense of [MFM, §4.6] $f_\lambda|W = \epsilon f_{\overline{\lambda}}$ for a non-zero constant ϵ .

By the way, here is a celebrated conjecture of Maeda:

Conjecture 4.14. *The Hecke algebra $h_{2k}(1; \mathbb{Q})$ is a single field K of degree $r := r(2k)$ over \mathbb{Q} whose Galois closure over \mathbb{Q} has Galois group isomorphic to the permutation group \mathfrak{S}_r of r letters.*

Moreover, it seems that $h_{2k}(1; \mathbb{Q})$ is generated by just $T(2)$ over \mathbb{Q} (see [M15] and [HM97]). By Corollary 4.9, $h_{2k}(1; \mathbb{Z})$ is generated over \mathbb{Z} by $T(p)$ for primes $p \leq r(2k)$.

4.3. Ramanujan’s congruence. Since Hecke operators preserve the space $S_{2k}(\mathrm{SL}_2(\mathbb{Z}))$ of cusp forms and by the dimension formula, $S_{12}(\mathrm{SL}_2(\mathbb{Z})) = \mathbb{C}\Delta$. Thus $\Delta|T(n) = \tau(n)\Delta$ and $\Delta = \sum_{n=1}^{\infty} \tau(n)q^n$ (by Lemma 4.3 and Corollary 4.8). We call such a modular form a Hecke eigenform. Since $T(m)T(n) = T(mn)$ as long as $(m, n) = 1$, we get

Theorem 4.15 (Mordell). *As long as $(m, n) = 1$, we have $\tau(m)\tau(n) = \tau(mn)$.*

We prove

Theorem 4.16. *We have $E_{12} \equiv \Delta \pmod{691}$.*

Proof. Consider $G_4^3 = 1 + \sum_{n=1}^{\infty} a_n q^n \in M_{12}(\mathrm{SL}_2(\mathbb{Z}); \mathbb{Z})$. Note that E_{12} and Δ are both Hecke eigenforms and form a basis of $M_k(\mathrm{SL}_2(\mathbb{Z}); \mathbb{Q})$. Thus we can write $G_4^3 = c(E_{12})E_{12} + c(\Delta)\Delta$. Looking at the constant term, we get

$$1 = a(0, G_4^3) = c(E_{12}) \frac{691}{2^2 \cdot 3^2 \cdot 5 \cdot 7 \cdot 13} + c(\Delta)0.$$

Thus $c(E_{12}) = \frac{2^2 \cdot 3^2 \cdot 5 \cdot 7 \cdot 13}{691}$. Now we look into the coefficient in q and get $c(E_{12}) + c(\Delta) = a(1, G_4^3) = 3 \cdot 240$ prime to 691, which implies that $c(\Delta)$ has denominator 691. In other words,

$$691c(E_{12})E_{12} + 691c(\Delta)\Delta = 691G_4^3 \equiv 0 \pmod{691},$$

and integers $691c(E_{12})$ and $691c(\Delta)$ is prime to 691. Comparing the coefficients in q , we get $E_{12} \equiv \Delta \pmod{691}$. \square

Here is a key fact:

Proposition 4.17. *Suppose that $h_k(N; \mathbb{Q})$ is semi-simple. For $\theta \in S_k(\Gamma_0(N); \mathbb{Z})$, if $\theta = \sum_{\lambda} c(\lambda) f_{\lambda}$ with $c(\lambda_0)$ having denominator \mathfrak{P} for $\lambda_0 \in \mathrm{Spec}(h_k(N; \mathbb{Z}))(\overline{\mathbb{Q}})$, then we have $\lambda \neq \lambda_0$ in $\mathrm{Spec}(h_k(N; \mathbb{Z}))(\overline{\mathbb{Q}})$ such that $f_{\lambda} \equiv f_{\lambda_0} \pmod{\mathfrak{P}}$.*

Proof. Suppose non-existence of λ_0 . We take sufficiently large valuation ring W in $\overline{\mathbb{Q}}$ associated to \mathfrak{P} . Then we have an operator $h \in h_k(N; W)$ such that its eigenvalue modulo the maximal ideal \mathfrak{m}_W of W are all distinct. Then the λ -eigenspace is $\mathrm{Ker}(h - \lambda(h))$. Similarly, we consider $H = \prod_{\lambda \neq \lambda_0} (h - \lambda(h))$. Then $S_k(\Gamma_0(N); W) \supset \mathrm{Ker}(H) \oplus \mathrm{Ker}(h - \lambda_0(h))$, and we have an exact sequence $0 \rightarrow \mathrm{ker}(H) \rightarrow S_k(\Gamma_0(N); W) \rightarrow W \rightarrow 0$. Note that $h - \lambda_0(h)$ is invertible on $\mathrm{Ker}(H)$, and hence give a unit multiple of the projection p_H of $S_k(\Gamma_0(N); W)$ to $\mathrm{Ker}(H)$. Thus $S_k(\Gamma_0(N); W) = \mathrm{Ker}(H) \oplus \mathrm{Ker}(h - \lambda_0(h))$. This shows that $\theta = p_H(\theta) + (\mathrm{id} - p_H)(\theta)$ with $p_H(\theta), (\mathrm{id} - p_H)(\theta) \in S_k(\Gamma_0(N); W)$. In other words, $c(\lambda_0)$ does not have denominator in W , a contradiction. \square

Corollary 4.18 (Ribet). *If p divides the denominator of $2^{-1}\zeta(1 - 2k)$, there exists a Hecke eigen cusp form f and a prime $\mathfrak{P}|p$ in $\overline{\mathbb{Q}}$ such that $f \equiv E_{2k} \pmod{\mathfrak{P}}$.*

As we will see soon, $h_{2k}(1; \mathbb{Q})$ is always semi-simple.

Proof. Write $2k = 4a + 6b$ for two non-negative integers a, b (a solution always exists). Take $\theta = G_4^a G_6^b$. Then for λ_0 with $E_{2k}|T(n) = \lambda_0(T(n))E_{2k}$, looking into the constant term, we have $c(\lambda_0) = 2\zeta(1 - 2k)^{-1}$ which has denominator p . Thus by Proposition 4.17, we have $f = f_{\lambda}$ such that $f \equiv E_{2k} \pmod{\mathfrak{P}}$. \square

4.4. Congruences and inner product. We suppose existence of a non-degenerate hermitian inner product satisfying the following conditions:

- (P1) $(\cdot, \cdot) : S_k(\Gamma_0(N)) \times S_k(\Gamma_0(N)) \rightarrow \mathbb{C}$ such that $(f|T(n), g) = (f, g|T(n))$ for all n ,
- (P2) $(f_{\lambda}, f_{\lambda}) \neq 0$ for each $\lambda \in \mathrm{Spec}(h_k(N; \mathbb{Z}))(\overline{\mathbb{Q}})$.

Here we say (\cdot, \cdot) is hermitian if $f \mapsto (f, g)$ is \mathbb{C} -linear and $\overline{(f, g)} = (g, f)$. Since for $f := f_{\lambda}$, we have

$$\lambda(T(n))(f, f) = (f|T(n), f) = (f, f|T(n)) = \overline{\lambda(T(n))}(f, f),$$

where \bar{x} indicates the complex conjugation of $x \in \mathbb{C}$, $(f_\lambda, f_\lambda) \neq 0$ implies $\lambda(T(n)) \in \mathbb{R}$. Thus $\mathbb{Q}(\lambda)$ is totally real. For $\mu, \lambda \in \text{Spec}(h_k(N; \mathbb{Z})(\overline{\mathbb{Q}}))$, we have

$$\mu(T(n))(f_\mu, f_\lambda) = (f_\mu|T(n), f_\lambda) = (f_\mu, f_\lambda|T(n)) = \lambda(T(n))(f_\mu, f_\lambda).$$

If $\mu \neq \lambda$, we find $T(n)$ such that $\mu(T(n)) \neq \lambda(T(n))$; so,

$$(f_\mu, f_\lambda) = \delta_{\mu, \lambda}(f_\lambda, f_\lambda).$$

Remark 4.2. If $\chi \neq \mathbf{1}$, λ may not be real valued.

Lemma 4.19. *Suppose that $h_k(N; \mathbb{Q})$ is semi-simple. For $\theta \in S_k(\Gamma_0(N))$, writing $\theta = \sum_{\lambda \in \text{Spec}(h_k(N; \mathbb{Z})(\overline{\mathbb{Q}}))} c_\lambda(\theta) f_\lambda$, we have $c_\lambda(\theta) = \frac{(\theta, f_\lambda)}{(f_\lambda, f_\lambda)}$.*

Proof. Let $h_k(N; \overline{\mathbb{Q}}) = \prod_\lambda \overline{\mathbb{Q}}$ where λ runs over $\text{Spec}(h_k(N; \overline{\mathbb{Q}})(\overline{\mathbb{Q}}))$. Let 1_λ be the idempotent of $h_k(N; \overline{\mathbb{Q}})$ corresponding to λ . Then for the pairing $\langle \cdot, \cdot \rangle$ between the Hecke algebra and the space of modular forms, the linear map $\ell : f \mapsto \langle 1_\lambda, f \rangle$ satisfies $\ell(f_\lambda) = \langle 1_\lambda, f \rangle = a(1, f|_\lambda|1_\lambda) = 1$ and $\ell(f|T(n)) = \lambda(T(n))\ell(f)$ for all $f \in S_k(\Gamma_0(N))$. Any linear map $L : S_k(\Gamma_0(N)) \rightarrow \mathbb{C}$ with $L(f|T(n)) = \lambda(T(n))L(f)$ is a constant multiple of ℓ and in fact, $L = L(f_\lambda)\ell$ as $\ell(f_\lambda) = 1$. Let $L(f) = (f, f_\lambda)$. Then

$$L(f|T(n)) = (f|T(n), f_\lambda) = (f, f_\lambda|T(n)) = \overline{\lambda(T(n))}L(f) = \lambda(T(n))L(f).$$

This shows that $L(f) = (f, f_\lambda) = (f_\lambda, f_\lambda)\ell(f)$. On the other hand, we have

$$L(\theta) = \sum_\mu c_\mu(\theta)(f_\mu, f_\lambda) = c_\lambda(\theta)(f_\lambda, f_\lambda).$$

Since $(f_\mu, f_\lambda) = \delta_{\mu, \lambda}(f_\lambda, f_\lambda)$, we conclude

$$c_\lambda(\theta) = \frac{(\theta, f_\lambda)}{(f_\lambda, f_\lambda)}.$$

□

Exercise 4.20. *Writing $\bar{\lambda}$ for the complex conjugation of $\lambda \in \text{Spec}(h_k(N, \chi; \mathbb{C}))(\mathbb{C})$, prove that $c_\lambda(\theta) = \frac{(\theta, f_{\bar{\lambda}})}{(f_\lambda, f_\lambda)} = \frac{(\theta, f_{\bar{\lambda}})}{(f_{\bar{\lambda}}, f_{\bar{\lambda}})}$ if $\chi \neq \mathbf{1}$.*

Exercise 4.21. *Instead of requiring the hermitian property, just assuming to have a non-degenerate bilinear pairing $\langle \cdot, \cdot \rangle : S_k(\Gamma_0(N)) \times S_k(\Gamma_0(N))$ satisfying (P1) and (P2) in place of (\cdot, \cdot) , prove the same formula as in the above lemma.*

Exercise 4.22. *Suppose that $h_k(N; \mathbb{Q})$ is semi-simple. Take the pairing $[\cdot, \cdot] : h_k(N; \mathbb{C}) \times h_k(N; \mathbb{C}) \rightarrow \mathbb{C}$ given by $[h, h'] = \text{Tr}(hh')$ for the trace map $\text{Tr} : h_k(N; \mathbb{C}) \rightarrow \mathbb{C}$. Prove the dual pairing of $S_k(\Gamma_0(N))$ of $[\cdot, \cdot]$ satisfies (P1–2).*

4.5. Petersson inner product. If $f \in S_k(\Gamma_0(N), \chi)$, we have $f|_\alpha = \sum_{n>0}^\infty a_n q^n$ and if $\alpha = 1$, we have $a_n = \int_0^1 f(z+u) \exp(-2\pi nu) du$. Using the above integral expression of a_n , we can prove the following facts (see [MFM, §2.1]):

- (1) $a_n = O(n^{k/2})$,
- (2) $|f(z) \operatorname{Im}(z)^{k/2}|$ is bounded over \mathfrak{H} if and only if f is a cusp form.

Since $f(q)$ is holomorphic on the open disk of radius 1 centered at 0 and vanishes at $q = 0$, it is bounded on an open disk centered at 0. Thus $|f(q)| = O(q)$, and hence $|f(z)|$ decays exponentially towards ∞ (i.e., if $\operatorname{Im}(z) \rightarrow \infty$). Then we get $\lim_{\operatorname{Im}(z) \rightarrow \infty} |(f|_\alpha(z)) \operatorname{Im}(z)^{k/2}| = 0$; so, for a cusp form f , $|f(z) \operatorname{Im}(z)^{k/2}|$ is bounded around all cusps of $X_0(N)$. This also follows from (1). Since

$$\alpha \begin{pmatrix} z & \bar{z} \\ 1 & 1 \end{pmatrix} = \begin{pmatrix} \alpha(z) & \overline{\alpha(z)} \\ 1 & 1 \end{pmatrix} \begin{pmatrix} j(\alpha, z) & 0 \\ 0 & j(\alpha, z) \end{pmatrix},$$

taking the determinant, we get

$$\det(\alpha) \operatorname{Im}(z) = \operatorname{Im}(\alpha(z)) |j(\alpha, z)|^2.$$

Thus $|f(z) \operatorname{Im}(z)^{k/2}|$ is a continuous function on the compact Riemann surface $X_0(N)$ if $f \in S_k(\Gamma_0(N), \chi)$. Since $\omega := y^{-2} dx \wedge dy = \frac{i}{2} y^{-2} dz \wedge d\bar{z}$ and $d\alpha(z) = j(\alpha, z)^{-2} dz$, we have $\omega \circ \alpha = \omega$; in particular, $y^{-2} dx dy$ is a measure on \mathfrak{H} invariant under $\operatorname{SL}_2(\mathbb{R})$. By Corollary 2.6, for a fundamental domain F of $\Gamma_0(N)$, the volume $\int_F y^{-2} dx dy$ is finite and independent of the choice of F .

Exercise 4.23. *Why is the volume $\int_F y^{-2} dx dy$ finite and independent of the choice of F ?*

Because of the above fact, for a function $f : X_0(N) \rightarrow \mathbb{C}$, we define

$$\int_{X_0(N)} f(z) y^{-2} dx dy := \int_F f(z) y^{-2} dx dy$$

writing $z = x + iy \in \mathfrak{H}$.

Take $f, g \in S_k(\Gamma_0(N), \chi)$. Then we see, for $\gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma_0(N)$,

$$(f\bar{g}) \circ \gamma = f(z) \chi(d) (cz + d)^k f(z) \overline{\chi(d) (cz + d)^k} = f\bar{g} |j(\gamma, z)|^{2k}.$$

In other words, $f\bar{g} \operatorname{Im}(z)^k : \mathfrak{H} \rightarrow \mathbb{C}$ factors through $X_0(N)$. Then we define the Petersson inner product on $S_k(\Gamma_0(N), \chi)$ by

$$(4.3) \quad \langle f, g \rangle = \int_{X_0(N)} f(z) \overline{g(z)} \operatorname{Im}(z)^{k-2} dx dy.$$

Plainly the Petersson inner product is positive definite hermitian form on $S_k(\Gamma_0(N), \chi)$. We quote another computational results from [MFM, §4.5–6] and [IAT, §3.4]:

Theorem 4.24. *Let the notation be as above. We have*

- (1) $\langle f|T(n), g \rangle = \langle f, g|T^*(n) \rangle$, where $T^*(n)$ is the Hecke operator associated to $\{\alpha' := \det(\alpha) \alpha^{-1} | \alpha \in \Delta_0(N), \det(\alpha) = n\}$,

(2) $T^*(n) = W \circ T(n) \circ W^{-1}$ for the Weil involution W .

Thus if $\chi = \mathbf{1}$, $(f, g) = \langle f, g \rangle$ satisfies (P1-2), and if $\chi \neq \mathbf{1}$, $(f, g) := \langle f, g_c | W \rangle$ for the Weil involution satisfies (P1-2), where $a(n, g_c) = \overline{a(n, g)}$ for “ $-$ ” indicating complex conjugation. Here is a brief sketch of a proof.

Proof. Let $\Gamma := \Gamma_0(N)$ and $\alpha \in \Delta_0(N)$. Then we put $\Gamma_\alpha := \alpha^{-1}\Gamma\alpha \cap \Gamma$. then $[\Gamma : \Gamma_\alpha] < \infty$. Decomposing $\Gamma = \bigsqcup_\delta \Gamma\delta$ and multiplying $\alpha^{-1}\Gamma\alpha$ from the left, we get

$$\alpha^{-1}\Gamma\alpha\Gamma = \alpha^{-1}\Gamma\alpha \cdot \left(\bigsqcup_\delta \Gamma\delta \right) = \alpha^{-1} \bigsqcup_\delta \Gamma\alpha\delta.$$

Thus we get $\Gamma\alpha\Gamma = \bigsqcup_\delta \Gamma\alpha\delta$. Similarly, if $\Gamma = \bigsqcup_\delta \delta\alpha\Gamma_\alpha\alpha^{-1}$, we have $\Gamma\alpha\Gamma = \bigsqcup_\delta \delta\alpha\Gamma$. Since $[\Gamma : \Gamma_\alpha] = [\Gamma : \alpha\Gamma_\alpha\alpha^{-1}]$ for $\alpha \in \Delta_0(N)$, we have $|\Gamma \backslash \Gamma\alpha\Gamma| = |\Gamma\alpha\Gamma/\Gamma|$ for $\alpha \in \Delta_0(N)$.

Suppose $d = |\Gamma \backslash \Gamma\alpha\Gamma| = |\Gamma\alpha\Gamma/\Gamma|$. Then we claim that $\Gamma\alpha\Gamma = \bigsqcup_\nu \Gamma\alpha_\nu \bigsqcup_\nu \alpha_\nu\Gamma$ for some common α_ν ($\nu = 1, 2, \dots, d$). Let us prove this. Pick a pair (i, j) with $1 \leq i, j \leq d$, and decompose $\Gamma\alpha\Gamma = \bigsqcup_{i=1}^d \Gamma\alpha_i = \bigsqcup_{j=1}^d \beta_j\Gamma$. If $\Gamma\alpha_i \cap \beta_j\Gamma = \emptyset$, $\Gamma\alpha_i \subset \bigcup_{k \neq j} \beta_k\Gamma$, and hence multiplying Γ from the right, we have $\Gamma\alpha\Gamma = \Gamma\alpha_i\Gamma \subset \bigcup_{k \neq j} \beta_k\Gamma$; so, $\Gamma\alpha\Gamma$ is a union of $d - 1$ right cosets, a contradiction. Thus we have $\Gamma\alpha_i \cap \beta_j\Gamma \neq \emptyset$, and picking $\gamma_i \in (\Gamma\alpha_i \cap \beta_j\Gamma)$, we find $\Gamma\alpha_i = \Gamma\gamma_i = \gamma_i\Gamma$ as desired.

By computation, writing $f \parallel_k \alpha := \det(\alpha)^{k/2} f(\alpha(z)) j(\alpha, z)^{-k}$,

$$\begin{aligned} [\Gamma : \Gamma_\alpha](f \parallel_k \alpha, g) &= \int_{\Gamma_\alpha \backslash \mathfrak{H}} f \parallel_k \alpha \bar{g} \operatorname{Im}(z)^k d\mu(z) \stackrel{\alpha(z) \mapsto z}{=} \\ &\int_{\alpha\Gamma_\alpha\alpha^{-1} \backslash \mathfrak{H}} f(z) \overline{g(\alpha^{-1}(z))} j(\alpha, \alpha^{-1}(z)) \operatorname{Im}(\alpha^{-1}(z))^k d\mu(z) = [\Gamma : \alpha\Gamma_\alpha\alpha^{-1}](f, g \parallel_k \alpha^{-1}). \end{aligned}$$

Since $[\Gamma : \Gamma_\alpha] = [\Gamma : \alpha\Gamma_\alpha\alpha^{-1}]$, we get $(f | [\Gamma\alpha\Gamma], g) = (f | [\Gamma\alpha^t\Gamma])$ for $\alpha^t = \det(\alpha)\alpha^{-1}$ as long as $|\Gamma \backslash \Gamma\alpha\Gamma| = |\Gamma\alpha\Gamma/\Gamma|$ taking the common left and right coset representatives. This is true for $\alpha \in \Delta_0(N)$ with $\det(\alpha)$ prime to N . Thus if $\Gamma\alpha\Gamma = \bigsqcup_\nu \Gamma\alpha_\nu = \bigsqcup_\nu \alpha_\nu\Gamma$, we have $\Gamma\alpha^t\Gamma = (\Gamma\alpha\Gamma)^t = \bigsqcup_\nu \Gamma\alpha'_\nu$, and this we obtain the first assertion. Since $\Gamma\tau\alpha\tau^{-1}\Gamma = \Gamma\alpha^t\Gamma$ for $\tau = \begin{pmatrix} 0 & 1 \\ N & 0 \end{pmatrix}$, we get the second formula as $f|W = f \parallel_k \tau$. \square

5. MODULAR L-FUNCTIONS

For $\lambda \in \operatorname{Spec}(h_k(N, \chi; \mathbb{Z}[\chi]))(\overline{\mathbb{Q}})$, we define $L(s, \lambda) = \sum_{n=1}^{\infty} \lambda(T(n))n^{-s}$. Then writing two roots of $X^2 - \lambda(T(p))X + \chi(p)p^{k-1} = 0$ as α_p, β_p for $p \nmid N$ and $\alpha_p = \lambda(U(p))$ with $\beta_p = 0$ for $p|N$, we get from Corollary 4.11

$$L(s, \lambda) = \sum_{n=1}^{\infty} \lambda(T(n))n^{-s} = \prod_p \sum_{j=0}^{\infty} \frac{\alpha_p^{j+1} - \beta_p^{j+1}}{\alpha_p - \beta_p} p^{-js}.$$

Note that

$$\sum_{j=0}^{\infty} (\alpha_p^{j+1} - \beta_p^{j+1}) p^{-js} = p^s \{ (1 - \alpha_p p^{-s})^{-1} - (1 - \beta_p p^{-s})^{-1} \} = \frac{\alpha_p - \beta_p}{(1 - \alpha_p p^{-s})(1 - \beta_p p^{-s})}.$$

Thus we get the Euler product expansion:

$$(5.1) \quad L(s, \lambda) = \prod_p \{(1 - \alpha_p p^{-s})(1 - \beta_p p^{-s})\}^{-1} = \prod_p \det(1 - \begin{pmatrix} \alpha_p & 0 \\ 0 & \beta_p \end{pmatrix} p^{-s})^{-1}.$$

Exercise 5.1. Give an explicit real number c such that the above Euler product converge if $\operatorname{Re}(s) > c$.

5.1. Rankin product L-functions. Consider the Dirichlet series

$$D(s, f, g) := \sum_{n=1}^{\infty} \bar{a}_n b_n n^{-s}$$

for $f = \sum_{n=1}^{\infty} a_n q^n \in S_k(\Gamma_0(N), \chi)$ and $g = \sum_{n=0}^{\infty} b_n q^n \in M_l(\Gamma_0(N), \psi)$. We study the Euler product of this L-function called the *Rankin product* of f and g .

Lemma 5.2. Suppose $f = f_{\bar{\lambda}}$ and $g = f_{\mu}$ for $\lambda \in \operatorname{Spec}(h_k(N, \chi^{-1}; \mathbb{Z}[\chi]))(\overline{\mathbb{Q}})$ and $\mu \in \operatorname{Spec}(h_l(N, \psi; \mathbb{Z}[\psi]))(\overline{\mathbb{Q}})$, and put $X^2 - \lambda(T(p))X + \chi(p)p^{k-1} = (X - \alpha_p)(X - \beta_p)$ and $X^2 - \mu(T(p))X + \chi(p)p^{k-1} = (X - \alpha'_p)(X - \beta'_p)$. Then we have

$$\begin{aligned} L(2 - k - l + 2s, \chi\psi)D(s, f, g) &= \prod_p \det(1 - \begin{pmatrix} \alpha_p & 0 \\ 0 & \beta_p \end{pmatrix} \otimes \begin{pmatrix} \alpha'_p & 0 \\ 0 & \beta'_p \end{pmatrix} p^{-s})^{-1} \\ &= \prod_p \{(1 - \alpha_p \alpha'_p p^{-s})(1 - \alpha_p \beta'_p p^{-s})(1 - \beta_p \alpha'_p p^{-s})(1 - \beta_p \beta'_p p^{-s})\}^{-1}. \end{aligned}$$

The Euler product converges absolutely and locally uniformly if $\operatorname{Re}(s) \gg 0$.

We define $L(s, \lambda \otimes \mu) := L(2 - k - l + 2s, \chi\psi)D(s, f, g)$.

Proof. The convergence follows from $|\lambda(T(p))| = O(p^{k/2})$ and $|\mu(T(p))| = O(p^{l-1+\epsilon})$ for any $\epsilon > 0$. We prove the factorization.

Put $P(X) = \sum_{n=1}^{\infty} \lambda(T(p^n))\mu(T(p^n))X^n$. Then we have, dropping the subscript “ p ”,

$$\begin{aligned} P(X) &= \frac{\sum_{n=0}^{\infty} (\alpha^{n+1} - \beta^{n+1})(\alpha'^{n+1} - \beta'^{n+1})X^n}{(\alpha - \beta)(\alpha' - \beta')} \\ &= \frac{1}{(\alpha - \beta)(\alpha' - \beta')X} \left\{ \frac{1}{1 - \alpha\alpha'X} - \frac{1}{1 - \alpha\beta'X} - \frac{1}{1 - \beta\alpha'X} + \frac{1}{1 - \beta\beta'X} \right\} \\ &= \frac{1 - \alpha\beta\alpha'\beta'X^2}{(1 - \alpha\alpha'X)(1 - \alpha\beta'X)(1 - \beta\alpha'X)(1 - \beta\beta'X)}. \end{aligned}$$

Since $\alpha\beta\alpha'\beta' = \chi\psi(p)p^{k+l-2}$, we get the formula. \square

Exercise 5.3. Compute Euler factorization of the triple product

$$\sum_{n=1}^{\infty} \lambda_1(T(n))\lambda_2(T(n))\lambda_3(T(n))n^{-s}$$

for $\lambda_j \in \operatorname{Spec}(h_{k_j}(N, \chi_j))$.

5.2. **Analyticity of $L(s, \lambda \otimes \mu)$.** Note that

$$(\bar{f}g) \circ \gamma = \bar{f}g\chi^{-1}\psi(\gamma)\overline{j(\gamma, z)^k}j(\gamma, z)^l = \bar{f}g\chi^{-1}\psi(\gamma)|j(\gamma, z)|^{2k}j(\gamma, z)^{l-k}$$

for $\gamma \in \Gamma_0(N)$. We compute

$$\int_0^\infty \int_0^1 \overline{f(z)}g(z)dx y^{s-1}dy = \int_{\Gamma_\infty \backslash \mathfrak{H}} \bar{f}gy^{s+1}d\mu(z)$$

for $d\mu(z) = y^{-2}dxdy$. Since

$$f\bar{g}(z) = \sum_{m=1, n=1}^\infty \bar{a}_n b_m \exp(2\pi i(mz - n\bar{z})) = \sum_{m=1, n=1}^\infty a_m \bar{b}_n \exp(2\pi i(n-m)x + (m+n)iy),$$

using the well known formula

$$\int_0^1 \exp(2\pi imx)dx = \begin{cases} 1 & \text{if } m = 0. \\ 0 & \text{if } m \neq 0, \end{cases}$$

we get

$$\int_0^1 f(z)\overline{g(z)}dx = \sum_{n=1}^\infty \bar{a}_n b_n \exp(-4\pi ny).$$

Then by the formula defining the Gamma function $\int_0^\infty \exp(-t)t^{s-1}dt = \Gamma(s)$, integrating \int_0^∞ , we get

$$\int_0^\infty \sum_{n=1}^\infty \bar{a}_n b_n \exp(-4\pi ny)y^{s-1}dy = (4\pi)^{-s}\Gamma(s) \sum_{n=1}^\infty \bar{a}_n b_n n^{-s} = (4\pi)^{-s}\Gamma(s)D(s, f, g).$$

Exercise 5.4. Justify the interchange of $\int_0^\infty \int_0^1$ and the summation $\sum_{m,n}$ if $\text{Re}(s) \gg 0$.

Note that $\Phi := \{z | 0 \leq x \leq 1 \text{ and } 0 < y < \infty\}$ is the fundamental domain of Γ_∞ . Thus Φ is equivalent to $\bigcup_{\gamma \in \Gamma_\infty \backslash \Gamma_0(N)} \gamma(F)$ for a fundamental domain F of $\Gamma_0(N)$ for the computation of integral. Thus we have

$$\int_{\Gamma_\infty \backslash \mathfrak{H}} \bar{f}gy^{s+1}d\mu(z) = \int_\Phi \bar{f}gy^{s+1}d\mu(z) = \sum_{\gamma \in \Gamma_\infty \backslash \Gamma_0(N)} \int_{\gamma(F)} \bar{f}gy^{s+1}d\mu(z).$$

By variable change $\gamma(z) \mapsto z$, we get

$$\begin{aligned} \int_{\gamma(F)} \bar{f}gy^{s+1}d\mu(z) &= \int_F \bar{f}(\gamma(z))g(\gamma(z))\text{Im}(\gamma(z))^{s+1}d\mu(z) \\ &= \int_F (\bar{f}g(\gamma(z))\chi^{-1}(\gamma)\overline{j(\gamma, z)^k} \psi(\gamma)j(\gamma, z)^l |j(\gamma, z)|^{-2(s+1)}y^{s+1}d\mu(z) \\ &= \int_F (\bar{f}g(\gamma(z))\chi^{-1}\psi(\gamma)j(\gamma, z)^{l-k} |j(\gamma, z)|^{2k-2(s+1)}y^{s+1}d\mu(z). \end{aligned}$$

Thus summing up over $\gamma \in \Gamma_\infty \backslash \Gamma_0(N)$, we get

$$(5.2) \quad (4\pi)^{-2s} \Gamma(s) D(s, f, g) \\ = \int_{X_0(N)} \bar{f} g E_{k-l, \chi \psi^{-1}}^*(s+1-k) y^{s+1} d\mu(z) = \langle g E_{k-l, \chi \psi^{-1}}^*(s+1-k) y^{s+1-k}, f \rangle.$$

This implies, by (2.13) and (2.6),

$$(5.3) \quad (4\pi)^{-2s} \Gamma(s) L(2s+l-k+2, \chi^{-1}\psi) D(s, f, g) \\ = 2^{-1} \int_{X_0(N)} \bar{f} g E'_{k-l, \chi \psi^{-1}}(s+1-k) y^{s+1} d\mu(z) \\ = G(\chi^{-1}\psi) \frac{(-2\pi i)^{k-l}}{N^{k-l} \Gamma(k-l)} \langle g E_{k-l, \chi \psi^{-1}}(s+1-k) y^{s+1-k}, f \rangle.$$

It is known (e.g., [MFM, Chapter 7] or [LFE, Chapter 9]) that $E_{k, \chi}(s)$ can be continued meromorphic function over \mathbb{C} having only pole at $s = 0, 1$ only when $k = 0$ and $\chi = 1$ giving for each s a slowly increasing function towards each cusp (as long as it is finite at s). Here a function $f(z)$ is slowly increasing towards each cusp means $|f|\alpha(z)|$ for each $\alpha \in SL_2(\mathbb{Q})$ has polynomial growth in $\text{Im}(z)$ as $\text{Im}(z) \rightarrow \infty$ (as long as $\text{Re}(z)$ is bounded). For a cusp from decay exponentially towards each cusp (said ‘‘rapidly decreasing’’), the above integral converges for any $s \in \mathbb{C}$ giving an entire function on \mathbb{C} as long as either $\chi \neq \psi$ or $k \neq l$. The L-function $L(s, \lambda \otimes \mu)$ has a nice functional equation of the form $s \leftrightarrow k+l+1-s$ (see [LFE, §9.5]).

5.3. Rationality of $L(s, \lambda \otimes \mu)$. If f_λ is primitive in the sense of [MFM, §4.6], we have $f_\lambda | W = W(\lambda) f_{\bar{\lambda}}$ for $W(\lambda) \in \mathbb{C}$ with $|W(\lambda)| = 1$. For simplicity, suppose that χ is a Dirichlet character of conductor C . Here is the rationality theorem of Shimura:

Theorem 5.5. *Suppose $f = f_{\bar{\lambda}}$ and $g = f_\mu$ for primitive $\lambda \in \text{Spec}(h_k(N, \chi^{-1}; \mathbb{Z}[\chi]))(\overline{\mathbb{Q}})$ and $\mu \in \text{Spec}(h_l(N, \psi; \mathbb{Z}[\psi]))(\overline{\mathbb{Q}})$. Then we have for all integer $l \leq m < k$,*

$$S(m, \lambda \otimes \mu) := \frac{\Gamma(m) \Gamma(m+1-l) L(m, \lambda \otimes \mu)}{N^{(k-l)} G(\chi^{-1}\psi) (2\pi i)^{k-l+2m} \langle f_\lambda, f_\lambda \rangle} \in \mathbb{Q}(\lambda, \mu),$$

and moreover for any $\sigma \in \text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$, we have

$$S(m, \lambda \otimes \mu)^\sigma = S(m, \lambda^\sigma \otimes \mu^\sigma).$$

Here $\mathbb{Q}(\lambda, \mu)$ is the subfield of $\overline{\mathbb{Q}}$ generated by $\lambda(T(n))$ and $\mu(T(n))$ for all n . We only prove this theorem for $N = 1$, $k > l + 2$ and $m = k - 1$. See [LFE, §10.2] for Shimura’s proof.

Proof. By (5.3) applied to $f = f_{\bar{\lambda}}$ and $g = f_\mu$, we have

$$\frac{\Gamma(k-l) \Gamma(s) L(s, \lambda \otimes \mu)}{N^{(k-l)} G(\chi^{-1}\psi) (2\pi i)^{k-l+2s}} = * \langle g E_{k-l, \chi^{-1}\psi^{-1}}(s+1-k) y^{s+1-k}, f_{\bar{\lambda}} \rangle,$$

where $*$:= $(-1)^{k-1}2^{-2(k-1)}$. Under the above simplifying conditions,

$$E_{k-l, \chi^{-1}\psi^{-1}}(0) = 2^{-1}L(1-k, \chi\psi) + \sum_{n=1}^{\infty} \sigma_{k-l-1, \chi\psi}(n)q^n \in \mathbb{Q}[\chi, \psi][[q]].$$

By Lemma 4.10, we have $\mathbb{Q}(\chi, \psi) \subset \mathbb{Q}(\lambda, \mu)$. Then putting $\theta = E_{k-l, \chi^{-1}\psi^{-1}}f_\mu$, we have, by Lemma 4.19,

$$S(k-1, \lambda \otimes \mu) = * \frac{\langle \theta, f_{\bar{\lambda}} \rangle}{\langle f_{\bar{\lambda}}, f_{\bar{\lambda}} \rangle} = * \cdot c_{\bar{\lambda}}(\theta) \in \mathbb{Q}(\lambda, \mu).$$

By Exercise 4.20, we have $\langle f_\lambda, f_\lambda \rangle = \langle f_{\bar{\lambda}}, f_{\bar{\lambda}} \rangle$. Then the rest follows from this formula. \square

Exercise 5.6. *Prove that $\mathbb{Q}(\lambda)$ is stable under complex conjugation and that for any embedding $\sigma : \mathbb{Q}(\lambda) \hookrightarrow \mathbb{C}$, we have $c \circ \sigma = \sigma \circ c$.*

5.4. Adjoint L-value and congruences. Define the following Euler product convergent absolutely if $\text{Re}(s) > 1$:

$$L(s, \text{Ad}(\lambda)) = \prod_p \left\{ \left(1 - \frac{\alpha_p}{\beta_p} p^{-s}\right) \left(1 - p^{-s}\right) \left(1 - \frac{\beta_p}{\alpha_p} p^{-s}\right) \right\}^{-1}.$$

Here $\lambda \in \text{Spec}(h_k(N, \chi; \mathbb{Z}[\chi]))(\overline{\mathbb{Q}})$. Put

$$\Gamma(s, \text{Ad}(\lambda)) = \Gamma_{\mathbb{C}}(s+k-1)\Gamma_{\mathbb{R}}(s+1),$$

where $\Gamma_{\mathbb{C}}(s) = 2(2\pi)^{-s}\Gamma(s)$ and $\Gamma_{\mathbb{R}}(s) = \pi^{-s/2}\Gamma(\frac{s}{2})$.

We have the following remarkable fact (which we prove in Spring 2017):

Theorem 5.7 (G. Shimura). *Let χ be a primitive character modulo N . Let $\lambda \in \text{Spec}(h_k(N, \chi; \mathbb{Z}[\chi]))(\mathbb{C})$ for $k \geq 1$. Then*

$$\Gamma(s, \text{Ad}(\lambda))L(s, \text{Ad}(\lambda))$$

has an analytic continuation to the whole complex s -plane and

$$\Gamma(1, \text{Ad}(\lambda))L(1, \text{Ad}(\lambda)) = 2^{k+1}N^{-1} \int_{\Gamma_0(N) \backslash \mathfrak{H}} |f|^2 y^{k-2} dx dy,$$

where $f = f_\lambda$ and $z = x + iy \in \mathfrak{H}$. If $N = 1$, we have the following functional equation:

$$\Gamma(s, \text{Ad}(\lambda))L(s, \text{Ad}(\lambda)) = \Gamma(1-s, \text{Ad}(\lambda))L(1-s, \text{Ad}(\lambda)).$$

Thus we get,

$$c_{\bar{\lambda}}(f_\mu E_{k-l, \chi^{-1}\psi^{-1}}) \doteq \frac{L(k-1, \lambda \otimes \mu)}{L(1, \text{Ad}(\lambda))},$$

whose denominator is the congruence prime of f_λ . By this, we could guess that congruence prime has to be the factor of $\frac{L(1, \text{Ad}(\lambda))}{\Omega}$ for a canonical period $\Omega \in \mathbb{C}^\times$ which is also the period of $L(k-1, \lambda \otimes \mu)$ up to some power of $2\pi i$ and the Gauss sum $G(\chi^{-1}\psi)$.
