

## Lecture 8 Hardness of DLP §2.6 & 2.7

Recall that  $DHP = EGP \leq DLP$ .

For the rest will be discussing how hard DLP is.

Recall that for any group  $G$ , there is a discrete log problem:

DLP Let  $g, h \in G$  where  $G$  is any group.

Let  $N = \text{ord}(g)$ . Find  $x \in \mathbb{Z}/N\mathbb{Z}$  st.  $g^x = h$ .

The methods we give this week work for any group, so they also apply to Elliptic Curve DHP & EGP.

When we get to RSA we will discuss methods that don't apply to Elliptic Curve RSA.

There is a fairly strong correspondence between techniques for factoring & techniques for discrete log, so these general group discrete log techniques can be adopted to

General RSA (both conventional & elliptic curve RSA).  
Similarly, the RSA  $\mathbb{F}_p^*$ -specific algorithms  
can be adapted to discrete log.

Method 1 Brute force.

Compute  $g^0, g^1, \dots, g^{N-1}$  until we find  $g^x = h$

Worst case: Need  $N-1$  multiplications.

If  $N$  has  $k$  bits,  $k \sim \log_2(N)$  so we need  
roughly  $N = O(2^k)$  operations.

Big O notation & Running time of Algorithms

$$f = O(g) \text{ if } \frac{f(k)}{g(k)} \leq C$$

For instance if  $\lim_{k \rightarrow \infty} \frac{f(k)}{g(k)}$  exists & is  $< \infty$ ,

$$f = O(g).$$

Ex  $f(k) = k^n, g(k) = a^k. \quad \lim_{k \rightarrow \infty} \frac{k^n}{a^k} = 0$

So  $f(k) = O(g(k)).$

Ex  $\sin(k) = \mathcal{O}(1)$  b/c  $\frac{\sin(k)}{1} \leq 1$  is bounded.

Def  $f(k) = \mathcal{o}(g(k))$  if  $g(k) = \Theta(f(k))$ .  
little  $\mathcal{O}$   $\uparrow$   $\leftarrow$  Big  $\mathcal{O}$

Def  $f$  has exponential growth if  $\exists a, b > 1$  s.t.  
 $f(k) = \mathcal{O}(a^k)$  &  $f(k) = \Omega(b^k)$   
(so  $f$  grows at least as fast as  $a^k$  & at most as fast as  $b^k$ )

Def  $f$  has subexponential growth if

$f(k) = \mathcal{O}(a^k)$  for all  $a > 1$  &

$f(k) = \Omega(k^n)$  for all  $n$ .

(so  $f$  grows faster than any polynomial & slower than any exponential function)

Def  $f$  has Polynomial growth if  $f(k) = O(k^n)$   
for some  $n$ .

We want to discuss the running time of algorithms.

Suppose we have an algorithm to compute something  
where if the input is size  $k$  the algorithm takes  $f(k)$   
steps.

•  $f(k)$  exponential growth: called an "exponential time  
algorithm"  
considered HARD.

•  $f(k)$  subexponential growth:  
called a "subexponential time algorithm"  
considered HARD

•  $f(k)$  polynomial growth  $\rightarrow$  "polynomial time algorithm"  
considered EASY.

Remark subexponential or exponential time only  
means asymptotically hard. Sometimes these work  
okay...

Rmk  $n^{1000}$  is asymptotically much smaller than  $2^n$  but will likely still be impractically slow in practice... still considered "EASY"

Trivial DLP algorithm runs in  $O(2^n)$  time.  
Slow! We will do a bit better.

## §2.7 Shank's Babystep - Giantstep algorithm.

$G$  a gp,  $g \in G$  of order  $N$ ,  $h \in G$ , want to solve  $g^x = h$ .

### Algorithm

① Set  $n = \lfloor \sqrt{N} \rfloor + 1$  e.g.  $N=30$ ,  $n = \lfloor \sqrt{30} \rfloor + 1 = 5 + 1 = 6$ .

② Create two lists:

List 1:  $g^0, g^1, \dots, g^{n-1}$  ( $n$  numbers) *babystep*

List 2:  $h, hg^{-n}, \dots, hg^{-(n-1)n}$  ( $n$  numbers) *giant step.*

(3) Find the collision between the two lists (guaranteed).  $g^i = h g^{-n_j}$

$$(4) h = g^{n_j + c} \Rightarrow x = n_j + c.$$

### Complexity

(2)  $\sim 2n$  multiplications to make the two lists.

(3) To find collision, essentially have to sort lists  $\rightarrow \mathcal{O}(n \log n) = \mathcal{O}(\sqrt{N} \log \sqrt{N})$

$$= \mathcal{O}(2^{k/2} \cdot k/2)$$

$$= \mathcal{O}(k 2^{k/2}).$$

Better than brute force, but still exponential time.

Ex In  $\mathbb{F}_{31}^*$ ,  $g=3$ ,  $\text{ord}(g)=30$ .

$$h=10.$$

Solve  $z^x=10$  in  $\mathbb{F}_{31}^*$ .

$$(1) n = \lfloor \sqrt{30} \rfloor + 1 = 6$$

$$(2) \text{List 1: } \begin{array}{cccccccc} g^0 & g^1 & g^2 & g^3 & g^4 & g^5 & g^6 & g^{-6} \\ || & || & || & || & || & || & || & || \\ 1 & 3 & 9 & 27 & 81 & 57 & 78 & 16 \\ || & || & || & || & || & || & || & || \\ & & & & 19 & 26 & 16 & 2 \end{array}$$

$$\text{List 2} \quad \begin{array}{cccc} h & hg^{-6} & hg^{-12} & hg^{-18} & hg^{-24} & hg^{-30} \\ || & || & || & & & \\ 10 & 20 & 40 & & & \\ || & || & || & & & \\ & & 9 & & & \end{array}$$

$$(3) g^2 = hg^{-12}$$

$$(4) h = g^{14} \Rightarrow x = 19.$$

# Correctness of Algorithm

Suppose  $x$  satisfies  $g^x = h$ . &  $0 \leq x \leq N-1$ .

Write  $x = nq + r$   $0 \leq r < n$  bound on  $r$ .

Want bound on  $q$ , too.

$$q = \frac{x-r}{n} < \frac{N-r}{n} \leq \frac{N}{n} < n$$

$$n = \lfloor \sqrt{N} \rfloor + 1 > \sqrt{N} \Rightarrow N < n^2 \Rightarrow \frac{N}{n} < n.$$

$$h = g^x = g^{nq+r} \Leftrightarrow h \cdot g^{-nq} = g^r$$

$g^r$  is in list 1 b/c  $0 \leq r < n$ .

$h \cdot g^{-nq}$  is in list 2 b/c  $0 \leq q < n$ .

$\Rightarrow$  must be a collision.
