POSITIVE DEPENDENCE FOR COLORED PERCOLATION

NIKITA GLADKOV∗ AND IGOR PAK∗

Abstract. For uniform random 4-colorings of graph edges with colors \{a, b, c, d\}, every two colors form a $\frac{1}{2}$-percolation, and every two overlapping pairs of colors form independent $\frac{1}{2}$-percolations. We show joint positive dependence for pairs of colors $ab$, $ac$ and $ac$, and joint negative dependence for pairs of colors $ab$, $ac$ and $bc$. The proof is based on a generalization of the Harris–Kleitman inequalities. We apply the results to crossing probabilities for the colored bond and site percolation, and to colored critical percolation that we also define.

Introduction. The study of percolation goes back to the 1957 paper by Broadbent and Hammersley [4] and has been incredibly popular in the last few decades across the sciences. It remains one of the most applied statistical models, reaching far corners of statistical physics and probability, and fields as disparate a materials science, network theory and seismology, see e.g. [15, 33, 27].

Despite remarkable recent advances, many problems remain open and continued to be actively pursued, see e.g. [2, 8, 16, 24]. Note that specific models of percolation vary greatly depending on the scientific context and applications. Here we consider the colored bond (site) percolation, where each graph edge (vertex) takes random color, see e.g. [22, 33, 36].

As one studies random events, one is naturally concerned about their correlations. The Fortuin–Kasteleyn–Ginibre (FKG) inequality [12] is a basic tool to establish positive dependence for percolation and related models, see e.g. [9, 25, 35]. This inequality shows that every two increasing (or two decreasing) random events are positively correlated (see below).

The FKG inequality is itself an advance generalization of the Harris–Kleitman inequality [18, 21] discovered independently in probability and graph theory. Outside of its fundamental applications to statistical physics and probability, it has numerous applications in graph theory [6, 19], order theory [10, 29] and algebraic combinatorics [5].

We are interested in generalizations of the Harris–Kleitman inequality to multiple functions, which has also been intensely studied but remains largely mysterious [13, 23, 26]. More precisely, we establish positive dependence for three pairwise independent percolations and generalize it further to $k$ percolations such that every $(k - 1)$ of them are mutually independent.

Positive correlation in percolation. We first illustrate the power of the Harris–Kleitman inequality. Let $G = (V, E)$ be a simple graph, which can be finite or infinite. Consider a $p$-percolation defined by independently at random deleting edges of $G$ with probability $(1 - p)$. We write $P_p(x \leftrightarrow y)$ for the probability that vertices $x, y \in V$ are connected.

In its basic application, the Harris–Kleitman inequality proves a positive correlation of connectivity of two pairs of vertices:

$$P_p(x \leftrightarrow y, u \leftrightarrow v) \geq P_p(x \leftrightarrow y) P_p(u \leftrightarrow v),$$

for all \(x, y, u, v \in V\). Equivalently, this says that the probability that two vertices are connected increases if some other two vertices are connected, even if these two vertices are quite far in the graph: \(\mathbb{P}_p(x \leftrightarrow y | u \leftrightarrow v) \geq \mathbb{P}_p(x \leftrightarrow y)\). This easily implies that the critical probability \(p_c = \sup \{p : \mathbb{P}_p(x \leftrightarrow y) = 0\}\) is independent on the vertex \(x\) in every connected graph, see e.g. \([3, 15]\). For the case when \(G = \mathbb{Z}^2\) is a square lattice, Harris proved that \(p_c \geq \frac{1}{2}\) in the original paper \([18]\). Famously, Kesten \([20]\) established the equality \(p_c = \frac{1}{2}\) twenty years later.

More generally, a subset \(A \subseteq 2^E\) is called closed upward, if \(A + e \in A\) for every \(A \in A\) and \(e \in E \setminus A\). Similarly, \(A\) is closed downward, if \(A - e \in A\) for every \(A \in A\) and \(e \in A\). We think of \(A\) as graph property, and write \(\mathbb{P}_p(A)\) for the probability that the property holds for a \(p\)-percolation. In this notation, the Harris–Kleitman inequality states that

\[
\mathbb{P}_p(A) \geq \mathbb{P}_p(A) \mathbb{P}_p(B),
\]

for every two closed upward \(A, B\). For \(A = \{H : x \leftrightarrow y\}\) and \(B = \{H : u \leftrightarrow v\}\) we obtain \([1]\). Note that \((2)\) holds also for every two closed downward \(A, B\).

**Positive dependence in colored percolation.** Let \(f : E \to \{a, b, c, d\}\) be a uniform random coloring of the edges of \(G\), where each edge is colored uniformly and independently. This gives a random partition \(E = E_a \sqcup E_b \sqcup E_c \sqcup E_d\), where \(E_s = f^{-1}(s)\) for a color \(s \in \{a, b, c, d\}\).

For every two distinct colors \(s, t \in \{a, b, c, d\}\), denote \(E_{st} := E_s \cup E_t\). One can think of \(E_{st}\) as either a \(\frac{1}{2}\)-percolation or a random uniform spanning subgraph of \(G\). Note that \(E_{ab}, E_{ac}\) and \(E_{bc}\) are pairwise independent, but not mutually independent. Our main result establishes their negative dependence:

**Theorem 1.** Let \(U, V, W\) be closed upward graph properties. Denote by \(U_{ab}, V_{ac}\) and \(W_{bc}\) the corresponding properties of \(E_{ab}\), \(E_{ac}\) and \(E_{bc}\), respectively. Then the events \(U_{ab}, V_{ac}\) and \(W_{bc}\) are pairwise independent, but

\[
\mathbb{P}(U_{ab} \cap V_{ac} \cap W_{bc}) \leq \mathbb{P}(U_{ab}) \mathbb{P}(V_{ac}) \mathbb{P}(W_{bc}),
\]

where the probability is over uniform random colorings \(f : E \to \{a, b, c, d\}\). Similarly,

\[
\mathbb{P}(U_{ab} \cap V_{ac} \cap W_{ad}) \geq \mathbb{P}(U_{ab}) \mathbb{P}(V_{ac}) \mathbb{P}(W_{ad}),
\]

where \(W_{ad}\) is the property of \(E_{ad}\).

Since all \(E_{st}\) are \(\frac{1}{2}\)-percolations, we can rewrite the RHS of both \((3)\) and \((4)\) as a more symmetric product:

\[
\mathbb{P}_\frac{1}{2}(U) \mathbb{P}_\frac{1}{2}(V) \mathbb{P}_\frac{1}{2}(W).
\]

For example, let \(E = \{e\}\), so that \(G\) is a graph with one edge, and let \(U = V = W\) be properties of containing \(e\). The LHS of \((3)\) is zero since we always have \(E_{ab} \cap E_{ac} \cap E_{bc} = \emptyset\). Similarly, the LHS of \((4)\) is \(\frac{1}{4}\) since \(E_{ab} \cap E_{ac} \cap E_{ad} = E_a\). On the other hand, the product \((5)\) is \(\frac{1}{8}\) since \(\mathbb{P}_\frac{1}{2}(U) = \mathbb{P}_\frac{1}{2}(V) = \mathbb{P}_\frac{1}{2}(W) = \frac{1}{2}\).

**Proof of Theorem 1.** Since \(E_{ab}\) and \(E_{ac}\) are independent \(\frac{1}{2}\)-percolations, this implies that events \(U_{ab}\) and \(V_{ac}\) are also independent. This proves the pairwise independence part.

We prove \((3)\) by induction on the number of edges in \(E\). For \(E = \emptyset\), the inequality is trivial. Fix an edge \(e \in E\). Consider the probability space of colorings of \(E - e\). For an event \(X_{ab} \subseteq 2^E\), denote by \(X_{ab}^+\) the subset of \(X_{ab}\) such that \(f(e) \in \{a, b\}\). Similarly, denote by \(X_{ab}^-\) the subset of \(X_{ab}\) such that \(f(e) \in \{c, d\}\).
By the symmetry, we have:
\[
\mathbb{P}(X_{ab} : f(e) = a) = \mathbb{P}(X_{ab} : f(e) = b) = 2\mathbb{P}^*_2(X^+) ,
\]
\[
\mathbb{P}(X_{ab} : f(e) = c) = \mathbb{P}(X_{ab} : f(e) = d) = 2\mathbb{P}^*_2(X^-) .
\]
Clearly, \( \mathbb{P}^*_2(X) = \mathbb{P}^*_2(X^-) + \mathbb{P}^*_2(X^+) \). When \( X \) is closed upward, we also have \( \mathbb{P}^*_2(X^-) \leq \mathbb{P}^*_2(X^+) \). We use this notation for \( X \in \{U, V, W\} \) and all pairs of colors.

Considering all possible colors of \( e \) and using the induction hypothesis, we have:
\[
\mathbb{P}(U_{ab} \cap V_{ac} \cap W_{bc}) = \mathbb{P}(U_{ab}^+ \cap V_{ac}^+ \cap W_{bc}^-) + \mathbb{P}(U_{ab}^+ \cap V_{ac}^- \cap W_{bc}^+) \\
+ \mathbb{P}(U_{ab}^- \cap V_{ac}^+ \cap W_{bc}^-) + \mathbb{P}(U_{ab}^- \cap V_{ac}^- \cap W_{bc}^+) \\
\leq 2\left( \mathbb{P}(U_{ab}^+) \mathbb{P}(V_{ac}^+) \mathbb{P}(W_{bc}^-) + \mathbb{P}(U_{ab}^+) \mathbb{P}(V_{ac}^-) \mathbb{P}(W_{bc}^+) \\
+ \mathbb{P}(U_{ab}^-) \mathbb{P}(V_{ac}^-) \mathbb{P}(W_{bc}^-) + \mathbb{P}(U_{ab}^-) \mathbb{P}(V_{ac}^-) \mathbb{P}(W_{bc}^-) \right).
\]
Simplifying the notation as above, the RHS is equal to:
\[
2\left( \mathbb{P}^*_2(U^+) \mathbb{P}^*_2(V^+) \mathbb{P}^*_2(W^-) + \mathbb{P}^*_2(U^+) \mathbb{P}^*_2(V^-) \mathbb{P}^*_2(W^+) \\
+ \mathbb{P}^*_2(U^-) \mathbb{P}^*_2(V^+) \mathbb{P}^*_2(W^+) + \mathbb{P}^*_2(U^-) \mathbb{P}^*_2(V^-) \mathbb{P}^*_2(W^-) \right) \\
= \left( \mathbb{P}^*_2(U^+) + \mathbb{P}^*_2(U^-) \right) \left( \mathbb{P}^*_2(V^+) + \mathbb{P}^*_2(V^-) \right) \left( \mathbb{P}^*_2(W^+) + \mathbb{P}^*_2(W^-) \right) \\
- \left( \mathbb{P}^*_2(U^+) - \mathbb{P}^*_2(U^-) \right) \left( \mathbb{P}^*_2(V^+) - \mathbb{P}^*_2(V^-) \right) \left( \mathbb{P}^*_2(W^+) - \mathbb{P}^*_2(W^-) \right) \\
\leq \mathbb{P}^*_2(U) \mathbb{P}^*_2(V) \mathbb{P}^*_2(W),
\]
as desired. The proof of (4) goes along the same lines.

\[\square\]

**Variations and generalizations.** First, note that we never use the graph structure, and the theorem can be viewed as a result about abstract set systems, cf. [1] [21]. In particular, it applies to the site percolation (see below). Note also that the theorem can be extended to the theorem can be viewed as an abstract set, cf. [1, 21]. In particular, it can be viewed as a result about abstract set systems, cf. [1, 21].

Curiously, for closed downward properties, the inequalities in the theorem hold reverse:
\[
\mathbb{P}(U_{ab} \cap V_{ac} \cap W_{bc}) \geq \mathbb{P}(U_{ab}) \mathbb{P}(V_{ac}) \mathbb{P}(W_{bc})
\]
and
\[
\mathbb{P}(U_{ab} \cap V_{ac} \cap W_{ad}) \leq \mathbb{P}(U_{ab}) \mathbb{P}(V_{ac}) \mathbb{P}(W_{ad}).
\]
The proofs follow verbatim the proofs in the theorem.

Next, we generalize the theorem to larger number of events. Start by taking \( k \) independent \( \frac{1}{2} \)-percolations \( E_1, \ldots, E_k \) on the same graph. Define a new \( \frac{1}{2} \)-percolation \( E_{k+1} \coloneqq \bigoplus E_i \pmod{2} \), where the edge \( e \) is present if and only if it is present in an odd number of \( E_i \)'s. Observe that every \( k \) of \( E_1, \ldots, E_{k+1} \) are mutually independent.

Then, for every closed downward properties \( X_1, \ldots, X_{k+1} \) we have:
\[
\mathbb{P}(X_1 \cap \cdots \cap X_{k+1}) \geq \mathbb{P}(X_1) \cdots \mathbb{P}(X_{k+1}).
\]
Once again, the proof follows verbatim the proof of the theorem.
Note that for \( k = 1 \), we have \( E_1 = E_2 \) and (8) is the Harris–Kleitman inequality (2). For \( k = 2 \), let

\[
f(e) := \begin{cases} 
  a & \text{if } e \in E_1 \cap E_2 \\
  b & \text{if } e \in E_1, e \notin E_2 \\
  c & \text{if } e \in E_2, e \notin E_1 \\
  d & \text{if } e \notin E_1, e \notin E_2 
\end{cases}
\]

Taking \( U := \mathcal{X}_1, V := \mathcal{X}_2 \) and \( W := \mathcal{X}_3 \), we have (8) coincides with (6).

Finally, one can easily obtain a colored version with \( m = 2^k \) colors. E.g., for \( k = 3 \), take a uniform random coloring \( f : E \to \{1, \ldots, 8\} \). Consider four pairwise independent \( \frac{1}{2} \)-percolations \( E_{1234}, E_{1256}, E_{1357} \) and \( E_{1467} \) with natural labeling. Note that every three of these are mutually independent. Then, for closed downward properties \( U, V, W \) and \( X \), the inequality (8) gives:

\[
\mathbb{P}(U_{1234} \cap V_{1256} \cap W_{1357} \cap X_{1467}) \geq \mathbb{P}(U_{1234}) \mathbb{P}(V_{1256}) \mathbb{P}(W_{1357}) \mathbb{P}(X_{1467}).
\]

**Probability of the majority.** The simplest nontrivial example in the theorem is when \( U = V = W \) is the property of having \( > m \) edges, where \( |E| = 2m + 1 \). The graph structure is irrelevant in this case, and we have \( \mathbb{P}_{\frac{1}{2}}(U_{ab}) = \frac{1}{2} \). A direct calculation in this case gives:

\[
\mathbb{P}(U_{ab} \cap V_{ac} \cap W_{bc}), \mathbb{P}(U_{ab} \cap V_{ac} \cap W_{ad}) \rightarrow \mathbb{P}_{\frac{1}{2}}(U)^3 = \frac{1}{8}
\]

as \( m \to \infty \). This shows that both (3) and (4) are asymptotically tight in this case.

**Crossing probabilities in a rectangle.** Let \( G = (V, E) \) be a \( n \times (n + 1) \) rectangle as in Figure 1. Consider a uniform random coloring \( f : E \to \{a, b, c, d\} \). Note that \( E_{ab}, E_{ac} \) and \( E_{ad} \) are pairwise independent bond \( \frac{1}{2} \)-percolations with free boundary conditions (BC). Let \( U = \{12 \leftrightarrow 34\} \) be the connectivity property of the opposite sides of \( G \), and recall that \( \mathbb{P}_{\frac{1}{2}}(U_{ab}) = \frac{1}{2} \), see e.g. [3]. Then (4) gives:

\[
\mathbb{P}(U_{ab} \cap U_{ac} \cap U_{ad}) \geq \mathbb{P}_{\frac{1}{2}}(U)^3 = \frac{1}{8},
\]

for all \( n \geq 1 \). On the other hand, by the pairwise independence we have:

\[
\mathbb{P}(U_{ab} \cap U_{ac} \cap U_{ad}) \leq \mathbb{P}(U_{ab} \cap U_{ac}) = \mathbb{P}_{\frac{1}{2}}(U)^2 = \frac{1}{4}.
\]

Note that as a function of \( p \) the crossing probability in a rhombus under \( p \)-percolation has a sharp threshold [3], so the trivial lower bound is unhelpful:

\[
\mathbb{P}(U_{ab} \cap U_{ac} \cap U_{ad}) \geq \mathbb{P}(U_a) = \mathbb{P}_{\frac{1}{4}}(U) \rightarrow 0 \text{ as } n \to \infty.
\]

For \( n = 30 \), the sampling of \( N = 4 \cdot 10^7 \) trials gives an approximation \( \mathbb{P}(U_{ab} \cap U_{ac} \cap U_{ad}) = 0.125098 \pm 0.000052 \). We conjecture that this probability is \( \frac{1}{8} \) in the limit \( n \to \infty \).

![Figure 1. Crossing probabilities in a rectangle, rhombus and a hexagon.](image-url)
Crossing probabilities in a rhombus. Let \( G = (V, E) \) be a \( m \)-rhombus on the triangular lattice, see Figure 1. Consider a uniform random coloring \( f : V \to \{a, b, c, d\} \). Note that \( V_{ab}, V_{ac} \) and \( V_{ad} \) are pairwise independent site \( \frac{1}{2} \)-percolations with free BC. Let \( U = \{12 \leftrightarrow 34\} \) and \( U' = \{14 \leftrightarrow 23\} \) be connectivity properties of the opposite sides of \( G \). Recall that \( \mathbb{P} \frac{1}{2}(U) + \mathbb{P} \frac{1}{2}(U') = 1 \) by a topological argument, so \( \mathbb{P} \frac{1}{2}(U) = \mathbb{P} \frac{1}{2}(U') = \frac{1}{2} \) by the symmetry. Then (3) and (4) give:

\[
\begin{align*}
\mathbb{P}(U_{ab} \cap U_{ac} \cap U_{bc}) &\leq \mathbb{P} \frac{3}{2}(U)^3 = \frac{1}{8}, \\
\mathbb{P}(U_{ab} \cap U_{ac} \cap U_{ad}) &\geq \mathbb{P} \frac{3}{2}(U)^3 = \frac{1}{8},
\end{align*}
\]

for all \( m \geq 1 \). We conjecture that

\[
\mathbb{P}(U_{ab} \cap U_{ac} \cap U_{bc}) \to \frac{1}{8} \quad \text{and} \quad \mathbb{P}(U_{ab} \cap U_{ac} \cap U_{ad}) \to \frac{1}{8} \quad \text{as} \quad m \to \infty.
\]

If this holds, we also have other similar limits, e.g.

\[
\mathbb{P}(U_{ab} \cap U_{ac} \cap U_{cd}) = \mathbb{P} \frac{3}{2}(U)^2 - \mathbb{P}(U_{ab} \cap U_{ac} \cap U_{ad}) \to \frac{1}{8}.
\]

This is in contrast with limits such as \( \mathbb{P}(U_{ab} \cap U_{bc} \cap U_{cd}) \) which can be computed by Watts’ formula \(34\) (see also \(7\), \(28\)). Finally, we note that \( \mathbb{P}(U_{ab} \cap U_{ac} \cap U_{ad}) \) is bounded away from zero. To see this, partition the rhombus into four parallelograms (see Figure 1), so the desired probability is bounded by the crossing probabilities:

\[
\mathbb{P}(U_{ab} \cap U_{ac} \cap U_{bc}) \geq 2 \mathbb{P} \frac{1}{2}(15 \leftrightarrow 46, 15 \leftrightarrow \infty) \mathbb{P} \frac{1}{2}(52 \leftrightarrow \infty) \geq 2 \frac{1}{165} \frac{1}{2} = \frac{1}{32}.
\]

This bound can be improved to \( \frac{9}{128} \) by a careful use of the inclusion-exclusion. In the limit \( m \to \infty \), this bound can be further improved since these crossing probabilities can be computed by Cardy’s formula \(3\), \(15\).

Crossing probabilities in a hexagon. Consider a regular hexagon \( G = (V, E) \) on the triangular lattice with side lengths \( \ell \), see Figure 1. Consider a site \( \frac{1}{2} \)-percolations with free BC as above. Let \( U := \{\exists x \in V : x \leftrightarrow 12, x \leftrightarrow 34, x \leftrightarrow 56\} \) be the joint connectivity property of the percolation graph. It was computed by Simmons \(30\) (see also \(11\)), that \( \mathbb{P} \frac{1}{2}(U) = 0.2556897... \) in the limit \( \ell \to \infty \). Consider a uniform random coloring \( f : V \to \{a, b, c, d\} \). Then (4) gives:

\[
\mathbb{P} \frac{1}{2}(U)^2 = 0.0653772... \geq \mathbb{P}(U_{ab} \cap U_{ac} \cap U_{ad}) \geq \mathbb{P} \frac{3}{2}(U)^3 = 0.016716...\]

in the limit \( \ell \to \infty \). Similarly, the inequality (3) gives:

\[
\mathbb{P}(U_{ab} \cap U_{ac} \cap U_{bc}) \leq \mathbb{P} \frac{3}{2}(U)^3 = 0.016716...\]

in the limit \( \ell \to \infty \). For \( \ell = 30 \), the sampling of \( N = 64000 \) trials gives \( \mathbb{P}(U_{ab} \cap U_{ac} \cap U_{ad}) = 0.0172 \pm 0.0005 \) and \( \mathbb{P}(U_{ab} \cap U_{ac} \cap U_{bc}) = 0.0166 \pm 0.0005 \). We conjecture that both probabilities are \( \mathbb{P} \frac{1}{2}(U)^3 = 0.016716... \) in the limit \( \ell \to \infty \).

New critical probability. Let \( G = (V, E) \) be an infinite connected graph. Consider a uniform random coloring \( f : E \to \{a, b, c, d\} \). For a vertex \( x \in V \), consider

\[
P(x) := \mathbb{P}(x \leftrightarrow_{ab} \infty, x \leftrightarrow_{ac} \infty, x \leftrightarrow_{ad} \infty),
\]

where \( x \leftrightarrow_{st} \infty \) means that \( x \) belongs to an infinite cluster of \( st \)-colored edges. Now (4) gives:

\[
\mathbb{P} \frac{1}{2}(x \leftrightarrow \infty)^2 \geq P(x) \geq \mathbb{P} \frac{1}{2}(x \leftrightarrow \infty)^3.
\]
Suppose \( G = (V, E) \) is a lattice with critical probability \( p_c < \frac{1}{2} \). For \( \alpha \in [0, \frac{1}{4}] \), consider a random 5-coloring \( f : E \to \{a, b, c, d, \diamond\} \), where the probabilities of colors \( a, b, c, d \) are \( \alpha \), and the probability of \( \diamond \) is \( (1 - 4\alpha) \). Then \( E_{ab}, E_{ac} \) and \( E_{ad} \) are pairwise independent \( 2\alpha \)-percolations. Denote by \( P_\alpha = P_\alpha(x) \) the probability given by (11) in this deformation. Define the following critical probability for the colored percolation:

\[
\alpha_c := \sup \{ \alpha : P_\alpha(x) = 0 \}.
\]

Now [12] implies that \( \alpha_c \leq \frac{1}{2} p_c \) while the examples above suggest \( \alpha_c = \frac{1}{2} p_c \). The numerical experiments also seem to confirm this. We tested the colored bond and site percolations on a triangular lattice with \( p_c = 2 \sin \frac{\pi}{18} = 0.3473... \) and \( p_c = \frac{1}{2} \), respectively [31]. Similarly, we tested the colored bond and site percolations on a cubic lattice \( G = \mathbb{Z}^3 \) with \( p_c = 0.2488... \) and \( p_c = 0.3116... \), respectively (see e.g. [32]). The results are given in Figure 2.

**Figure 2.** Colored bond/site percolations in triangular and cubic lattices.

**Conclusions.** The subject of positive dependence for colored percolation is largely unexplored and can be viewed as a special case of algebraic inequalities for cumulants of positive functions. The latter has been actively studied (see [13, 23] for recent references), but the type of inequalities we consider are new.

In full generality, our results extend the Harris–Kleitman inequality (2) to multiple pairwise independent events. This allows us to give lower and upper bounds on the mutual dependence of these events, and to define critical constants \( \alpha_c \) for a deformation of the colored percolation. Our lower and upper bounds are asymptotically tight for the conjectured crossing probabilities of the colored percolation on lattices, exhibiting the same phenomenon as the majority property.

**Acknowledgements.** We are grateful to Matija Bucić, Swee Hong Chan, Tom Hutchcroft, Jeff Kahn and Bhargav Narayanan for interesting conversations on the subject. Special thanks to Geoffrey Grimmett and Bob Ziff for helpful remarks on the paper, and to Aleksandr Zimin for help with numerical experiments. The second author was partially supported by the NSF.
